# 1 Basic set theory and numbers

In this chapter, we discuss informally some of the basic notions in set theory and basic properties about numbers. A more thorough treatment can be found in [Mun, Ch. 1] (for set theory) and [Rud-P, Ch. 1] (for numbers).

Let me first list the notations and conventions that will be used throughout the notes. We use frequently the abbreviations:

iff=if and only if  
LHS=left hand side      RHS=right hand side  
 $\exists$ =there exists       $\forall$ =for all  
i.e.=in other words      e.g.=for example  
cf.=compare/check/see/you are referred to  
resp.=respectively      WLOG=without loss of generality

If  $P, Q$  are properties, then

$$P \wedge Q = P \text{ and } Q \quad P \vee Q = P \text{ or } Q \quad \neg P = \text{Not } P$$

If  $\mathbb{F}$  is any field (e.g.  $\mathbb{Q}, \mathbb{R}, \mathbb{C}$ ), we let  $\mathbb{F}^\times = \mathbb{F} \setminus \{0\}$ . If  $\alpha$  is a complex number and  $n \in \mathbb{N}$ , we define the **binomial coefficient**

$$\binom{\alpha}{n} = \begin{cases} \frac{\alpha \cdot (\alpha - 1) \cdots (\alpha - n + 1)}{n!} & \text{if } n \geq 1 \\ 1 & \text{if } n = 0 \end{cases} \quad (1.1)$$

where  $n! = n(n-1)(n-2) \cdots 2 \cdot 1$  and  $0! = 1$ .

Topics marked with **★** are technical and/or their methods are rarely used in later studies. You can skim or skip them on first reading. Topics marked with **\*** are interesting, but not necessarily technical or difficult. They are not essential for understanding the later part of the notes.

## 1.1 Basic operations and axioms

Intuitively, a set denotes a collection of elements. For instance:

$$\mathbb{Z} = \{\text{all integers}\} \quad \mathbb{N} = \mathbb{Z}_{\geq 0} = \{n \in \mathbb{Z} : n \geq 0\} \quad \mathbb{Z}_+ = \{n \in \mathbb{Z} : n > 0\}$$

have infinitely many elements. (In this course, we will not be concerned with the rigorous construction of natural numbers and integers from Peano axioms.) We also let

$$\mathbb{Q} = \{\text{all rational numbers}\} \quad \mathbb{R} = \{\text{all real numbers}\}$$

if we that rational and real numbers exist and satisfy the properties we are familiar with in high school mathematics. (We will construct  $\mathbb{Q}$  and  $\mathbb{R}$  rigorously, by the way.)

Set theory is the foundation of modern mathematics. It consists of several Axioms telling us what we can do about the sets. For example, the following way of describing sets

$$\{x : x \text{ satisfies property...}\} \quad (1.2)$$

is illegal, since it gives **Russell's paradox**: Consider

$$S = \{A : A \text{ is a set and } A \notin A\} \quad (1.3)$$

If  $S$  were a set, then  $S \in S \Rightarrow S \notin S$  and  $S \notin S \Rightarrow S \in S$ . This is something every mathematician doesn't want to happen.

Instead, the following way of defining sets is legitimate:

$$\{x \in X : x \text{ satisfies property } \dots\} \quad (1.4)$$

where  $X$  is a given set. For instance, we can define the **difference** of two sets:

$$A \setminus B = A - B = \{x \in A : x \notin B\}$$

So let us figure out the legal way of defining unions and intersections of sets. The crucial point is that we assume the following axiom:

**Axiom.** If  $\mathcal{A}$  is a set of sets, then there exists a set  $X$  such that  $A \subset X$  for all  $A \in \mathcal{A}$ .

Thus, if  $\mathcal{A}$  is a set of sets, let  $X$  satisfy  $A \subset X$  for all  $A \in \mathcal{A}$ , then we can define the **union** and the **intersection**

$$\bigcup_{A \in \mathcal{A}} A = \{x \in X : \text{there exists } A \in \mathcal{A} \text{ such that } x \in A\} \quad (1.5a)$$

$$\bigcap_{A \in \mathcal{A}} A = \{x \in X : \text{for all } A \in \mathcal{A} \text{ we have } x \in A\} \quad (1.5b)$$

It is clear that this definition does not rely on the particular choice of  $X$ .

**Remark 1.1.** In many textbooks, it is not uncommon that sets are defined as in (1.2). You should interpret such definition as (1.4), where the set  $X$  is omitted because it is clear from the context. For instance, if the context is clear, the set  $\{x \in \mathbb{R} : x \geq 0\}$  could be simply written as  $\{x : x \geq 0\}$  or even  $\{x \geq 0\}$ . By the same token, the phrase " $\in X$ " in (1.5) could be omitted. So we can also write

$$A \cup B = \{x : x \in A \text{ or } x \in B\} \quad A \cap B = \{x : x \in A \text{ and } x \in B\}$$

which are special cases of (1.5).

**Remark 1.2.** In the same spirit, when discussing subsets of a given “large” set  $X$ , and if  $X$  is clear from the context, we shall write  $X \setminus A$  (where  $A \subset X$ ) as  $A^c$  and call it the **complement** of  $A$ .

**Example 1.3.** We have

$$\bigcup_{x \in (1, +\infty)} [0, x) = [0, +\infty) \quad \bigcap_{n \in \mathbb{Z}_+} (0, 1 + 1/n) = (0, 1] \quad \bigcup_{n \in \mathbb{N}} (0, 1 - 1/n] = (0, 1)$$

The readers may notice that these examples are not exactly in the form (1.5). They are actually unions and intersections of indexed families of sets. (See Def. 1.10.) We need some preparation before discussing this notion.

**Axiom.** If  $A_1, \dots, A_n$  are sets, their **Cartesian product** exists:

$$A_1 \times \cdots \times A_n = \{(a_1, \dots, a_n) : a_i \in A_i \text{ for all } 1 \leq i \leq n\}$$

where two elements  $(a_1, \dots, a_n)$  and  $(b_1, \dots, b_n)$  of the Cartesian product are regarded equal iff  $a_1 = b_1, \dots, a_n = b_n$ . We also write

$$(a_1, \dots, a_n) = a_1 \times \cdots \times a_n$$

especially when  $a, b$  are real numbers and  $(a, b)$  can mean an open interval. We understand  $A_1 \times \cdots \times A_n$  as  $\emptyset$  if some  $A_i$  is  $\emptyset$ .

If  $A_1 = \cdots = A_n = A$ , we write the Cartesian product as  $A^n$ . □

**Example 1.4.** Assume that the set of real numbers  $\mathbb{R}$  exists. Then the set of complex numbers  $\mathbb{C}$  is defined to be  $\mathbb{R}^2 = \mathbb{R} \times \mathbb{R}$  as a set. We write  $(a, b) \in \mathbb{C}$  as  $a + bi$  where  $a, b \in \mathbb{R}$ . Define

$$\begin{aligned} (a + bi) + (c + di) &= (a + c) + (b + d)i \\ (a + bi) \cdot (c + di) &= (ac - bd) + (ad + bc)i \end{aligned}$$

Define the zero element  $0$  of  $\mathbb{C}$  to be  $0 + 0i$ . More generally, we consider  $\mathbb{R}$  as a subset of  $\mathbb{C}$  by viewing  $a \in \mathbb{R}$  as  $a + 0i \in \mathbb{C}$ . This defines the usual arithmetic of complex numbers.

If  $z = a + bi$ , we define its **absolute value**  $|z| = \sqrt{a^2 + b^2}$ . Then  $z = 0$  iff  $|z| = 0$ . We define the **(complex) conjugate** of  $z$  to be  $\bar{z} = a - bi$ . Then  $|z|^2 = z\bar{z}$ .

If  $z \neq 0$ , then there clearly exists a unique  $z^{-1} \in \mathbb{C}$  such that  $zz^{-1} = z^{-1}z = 1$ :  $z^{-1} = |z|^{-2} \cdot \bar{z}$ . Thus, using the language of modern algebra,  $\mathbb{C}$  is a **field**.<sup>1</sup> □

---

<sup>1</sup>See Rem. 6.7 or [Rud-P, Def. 1.12] for the definition of fields. Rather than memorizing the full definition of fields, it is more important to keep in mind some typical (counter)examples:  $\mathbb{Q}, \mathbb{R}, \mathbb{C}$  are fields.  $\mathbb{Z}$  is not a field, because not every non-zero element of  $\mathbb{Z}$  has an inverse. The set of quaternions  $\{a + bi + cj + dk : a, b, c, d \in \mathbb{R}\}$  is not a field because it is not commutative ( $ij = -ji = k$ ). The set of rational functions  $P(x)/Q(x)$ , where  $P, Q$  are polynomials with coefficients in  $\mathbb{R}$  and  $Q \neq 0$ , is a field.

The axiom of Cartesian product allows us to define relations and functions:

**Definition 1.5.** If  $A, B$  are sets, a subset  $R$  of  $A \times B$  is called a **relation**. For  $(a, b) \in A \times B$ , we write  $aRb$  iff  $(a, b) \in R$ . We understand “ $aRb$ ” as “ $a$  is related to  $b$  through the relation  $R$ ”.

**Definition 1.6.** A relation  $f$  of  $A, B$  is called a **function** or a **map** (or a **mapping**), if for every  $a \in A$  there is a unique  $b \in B$  such that  $aRb$ . In this case, we write  $b = f(a)$ .

When we write  $f : A \rightarrow B$ , we always mean that  $A, B$  are sets and  $f$  is a function from  $A$  to  $B$ .  $A$  and  $B$  are called respectively the **domain** and the **codomain** of  $f$ . (Sometimes people also use the words “source” and “target” to denote  $A$  and  $B$ .)

If  $E \subset A$  and  $F \subset B$ , we define the **image under  $f$**  of  $E$  and the **preimage under  $f$**  of  $F$  to be

$$\begin{aligned} f(E) &= \{b \in B : \exists a \in E \text{ such that } b = f(a)\} \\ f^{-1}(F) &= \{a \in A : f(a) \in F\}. \end{aligned}$$

$f(A)$  is simply called the **image** of  $f$ , or the **range** of  $f$ . If  $b \in B$ ,  $f^{-1}(\{b\})$  is often abbreviated to  $f^{-1}(b)$ . The function

$$f|_E : E \rightarrow B \quad x \mapsto f(x)$$

is called the **restriction** of  $f$  to  $E$ . □

The intuition behind the definition of functions is clear: we understand functions as the same as their graphs. So a subset  $f$  of the “coordinate plane”  $A \times B$  is the graph of a function iff it “intersects every vertical line precisely once”.

**Remark 1.7.** According to our definition,  $\emptyset$  (as a subset of  $\emptyset \times B$ ) is the only function from  $\emptyset$  to  $B$ . (A false assumption implies any statement.) If  $A \neq \emptyset$ , there are no functions  $A \rightarrow \emptyset$ .

**Definition 1.8.** A function  $x : \mathbb{Z}_+ \rightarrow A$  is called a **sequence in  $A$** . We write  $x(n)$  as  $x_n$ , and write this sequence as  $(x_n)_{n \in \mathbb{Z}_+}$  (or simply  $(x_n)_n$  or  $(x_n)$ ).

Many people write such a sequence as  $\{x_n\}_{n \in \mathbb{Z}_+}$ . We do not use this notation, since it can be confused with  $\{x_n : n \in \mathbb{Z}_+\}$  (the range of the function  $x$ ).

**Axiom.** If  $X$  is a set, then the **power set**  $2^X$  exists, where

$$2^X = \{\text{Subsets of } X\}$$

**Example 1.9.** The set  $2^{\{1,2,3\}}$  has 8 elements:  $\emptyset, \{1\}, \{2\}, \{3\}, \{1,2\}, \{1,3\}, \{2,3\}, \{1,2,3\}$ . Surprisingly,  $8 = 2^3$ . As we shall see in Exp. 1.54 and Cor. 1.57, this relationship holds more generally, which explains the terminology  $2^X$ .

Now we are ready to define indexed families of sets.

**Definition 1.10.** An **indexed family of sets**  $(S_i)_{i \in I}$  is defined to be a function  $S : I \rightarrow 2^X$  for some sets  $I, X$ . We write  $S(i)$  as  $S_i$ . (So  $S_i$  is a subset of  $X$ .)  $I$  is called the **index set**. Define

$$\bigcup_{i \in I} S_i = \bigcup_{T \in S(I)} T \quad \bigcap_{i \in I} S_i = \bigcap_{T \in S(I)} T$$

Note that  $S(I)$  is the image of the function  $S$ .

**Example 1.11.** In the union  $\bigcup_{x \in (1, +\infty)} [0, x)$ , the index set is  $I = (1, +\infty)$ , and  $X$  can be the set of real numbers  $\mathbb{R}$ . Then  $S : I \rightarrow 2^X$  is defined to be  $S_i = S(i) = [0, i)$ .

**Exercise 1.12.** Let  $f : A \rightarrow B$  be a function. We say that  $f$  is **injective** if for all  $a_1, a_2 \in A$  satisfying  $a_1 \neq a_2$  we have  $f(a_1) \neq f(a_2)$ . We say that  $f$  is **surjective** if for each  $b \in B$  we have  $f^{-1}(b) \neq \emptyset$ .  $f$  is called **bijective** if it is both surjective and injective. Define the **identity maps**  $\text{id}_A : A \rightarrow A, a \mapsto a$  and  $\text{id}_B$  in a similar way. Prove that

$$f \text{ is injective} \iff \text{there is } g : B \rightarrow A \text{ such that } g \circ f = \text{id}_A \quad (1.6a)$$

$$f \text{ is surjective} \iff \text{there is } g : B \rightarrow A \text{ such that } f \circ g = \text{id}_B \quad (1.6b)$$

$$f \text{ is bijective} \iff \text{there is } g : B \rightarrow A \text{ such that } g \circ f = \text{id}_A \text{ and } f \circ g = \text{id}_B \quad (1.6c)$$

Show that the  $g$  in (1.6a) (resp. (1.6b), (1.6c)) is surjective (resp. injective, bijective).

The equivalence (1.6b) is subtler, since its proof requires Axiom of Choice.

**Axiom.** Let  $(S_i)_{i \in I}$  be an indexed family of sets. The **Axiom of Choice** asserts that if  $S_i \neq \emptyset$  for all  $i \in I$ , then there exists a function (the **choice function**)

$$f : I \rightarrow \bigcup_{i \in I} S_i$$

such that  $f(i) \in S_i$  for each  $i \in I$ .

Intuitively, the axiom of choice says that for each  $i \in I$  we can choose an element  $f(i)$  of  $S_i$ . And such choice gives a function  $f$ .

**Example 1.13.** Let  $f : A \rightarrow B$  be surjective. Then each member of the family  $(f^{-1}(b))_{b \in B}$  is nonempty. Thus, by axiom of choice, there is a choice function  $g$  defined on the index set  $B$  such that  $g(b) \in f^{-1}(b)$  for each  $b$ . Clearly  $f \circ g = \text{id}_B$ .

**Remark 1.14.** Suppose that each member  $S_i$  of the family  $(S_i)_{i \in I}$  has exactly one element. Then the existence of a choice function does not require Axiom of Choice: Let  $X = \bigcup_{i \in I} S_i$  and define relation

$$f = \{(i, x) \in I \times X : x \in S_i\}$$

Then one checks easily that this relation between  $I$  and  $X$  is a function, and that it is the (necessarily unique) choice function of  $(S_i)_{i \in I}$ .

According to the above remark, one does not need Axiom of Choice to prove (1.6a) and (1.6c). Can you see why?

## 1.2 Partial and total orders, equivalence relations

**Definition 1.15.** Let  $A$  be a set. A **partial order** (or simply an **order**)  $\leq$  on  $A$  is a relation on  $A \times A$  satisfying for all  $a, b, c \in A$  that:

- (Reflexivity)  $a \leq a$ .
- (Antisymmetry) If  $a \leq b$  and  $b \leq a$  then  $a = b$ .
- (Transitivity) If  $a \leq b$  and  $b \leq c$  then  $a \leq c$ .

We write  $b \geq a$  iff  $a \leq b$ . Write  $a > b$  iff  $a \geq b$  and  $a \neq b$ . Write  $a < b$  iff  $b > a$ . So  $\geq$  is also an order on  $A$ . The pair  $(A, \leq)$  is called a **partially ordered set**, or simply a **poset**. A partial order  $\leq$  on  $A$  is called a **total order**, if for every  $a, b \in A$  we have either  $a \leq b$  or  $b \leq a$ .

**Example 1.16.** The following are examples of orders.

- Assume that  $\mathbb{R}$  exists. Then  $\mathbb{R}$  has the canonical total order, which restricts to the total order of  $\mathbb{Z}$ . This is the total order that everyone is familiar with.
- Let  $X$  be a set. Then  $(2^X, \subset)$  is a poset.
- $\mathbb{R}^2$  is a poset, if we define  $(a, b) \leq (c, d)$  to be  $a \leq c$  and  $b \leq d$ .

**Definition 1.17.** A relation  $\sim$  on a set  $A$  is called an **equivalence relation**, if for all  $a, b, c \in A$  we have

- (Reflexivity)  $a \sim a$ .
- (Symmetry)  $a \sim b$  iff  $b \sim a$ .
- (Transitivity) If  $a \sim b$  and  $b \sim c$  then  $a \sim c$ .

Later, we will use the notions of partial orders and equivalence relation not just for a set, but for a collection of objects “larger” than a set. See Sec. 1.4.

**Definition 1.18.** Let  $A$  be a set, together with an equivalence relation  $\sim$ . Define a new set

$$A/\sim = \{[a] : a \in A\}$$

where the notion  $[a]$  can be understood in the following two equivalent ways (we leave it to the readers to check the equivalence):

- (1)  $[a]$  is a new symbol. We understand  $[a]$  and  $[b]$  as equal iff  $a \sim b$ .
- (2)  $[a] = \{x \in A : x \sim a\}$

We call  $[a]$  the **equivalence class** (or the **residue class**) of  $a$ , and call  $A/\sim$  the **quotient set** of  $A$  under  $\sim$ . The surjective map  $\pi : a \in A \mapsto [a] \in A/\sim$  is called the **quotient map**.

**Exercise 1.19.** Prove that every surjective map is equivalent to a quotient map. More precisely, prove that for every surjection  $f : A \rightarrow B$ , there is an equivalence relation  $\sim$  on  $A$  and a bijective map  $\Phi : A/\sim \rightarrow B$  such that the following diagram commutes (i.e.  $f = \Phi \circ \pi$ ):

$$\begin{array}{ccc} & A & \\ \pi \swarrow & & \searrow f \\ A/\sim & \xrightarrow{\Phi} & B \end{array} \quad (1.7)$$

This is the first time we see commutative diagrams. Commutative diagrams are very useful for indicating that certain maps between sets are “equivalent” or are satisfying some more general relations. For example, (1.7) shows that the maps  $f$  and  $\pi$  are equivalent, and that this equivalence is implemented by the bijection  $\Phi$ . The formal definition of commutative diagrams is the following:

**Definition 1.20.** A diagram (i.e. some sets denoted by symbols, and some maps denoted by arrows) is called a **commutative diagram**, if all directed paths in the diagram with the same start and endpoints lead to the same result.

Here is an example of commutative diagram in linear algebra. This example assumes some familiarity with the basic properties of vector spaces and linear maps.<sup>2</sup>

**Example 1.21.** Let  $V, W$  be vector spaces over a field  $\mathbb{F}$  with finite dimensions  $m, n$  respectively. Let  $e_1, \dots, e_m$  be a basis of  $V$ , and let  $\varepsilon_1, \dots, \varepsilon_n$  be a basis of  $W$ . We know that there are unique linear isomorphisms  $\Phi : \mathbb{F}^m \xrightarrow{\sim} V$  and  $\Psi : \mathbb{F}^n \xrightarrow{\sim} W$  such that

$$\Phi(a_1, \dots, a_m) = a_1 e_1 + \dots + a_m e_m \quad \Psi(b_1, \dots, b_n) = b_1 \varepsilon_1 + \dots + b_n \varepsilon_n$$

Let  $T : V \rightarrow W$  be a **linear map**, i.e., a map satisfying  $T(a\xi + b\eta) = aT\xi + bT\eta$  for all  $a, b \in \mathbb{F}, \xi, \eta \in V$ . Then there is a unique  $n \times m$  matrix  $A \in \mathbb{F}^{n \times m}$  (viewed as a linear map  $\mathbb{F}^m \rightarrow \mathbb{F}^n$  defined by matrix multiplication) such that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{F}^m & \xrightarrow[\simeq]{\Phi} & V \\ A \downarrow & & \downarrow T \\ \mathbb{F}^n & \xrightarrow[\simeq]{\Psi} & W \end{array} \quad (1.8)$$

---

<sup>2</sup>Again, we refer the readers to Internet or any Linear Algebra textbook (e.g. [Axl]) for the definition of vector spaces and linear maps.

namely,  $T\Phi = \Psi A$ . This commutative diagram tells us that  $T$  is equivalent to its **matrix representation**  $A$  under the bases  $e_\bullet, \varepsilon_\star$ , and that this equivalence is implemented by the linear isomorphisms  $\Phi$  (on the sources) and  $\Psi$  (on the targets).

Commutative diagrams are ubiquitous in mathematics. You should learn how to read commutative diagrams and understand their intuitive meanings. We will see more examples in the future of this course.

### 1.3 $\mathbb{Q}, \mathbb{R}$ , and $\overline{\mathbb{R}} = [-\infty, +\infty]$

Using equivalence classes, one can construct rational numbers from integers, and real numbers from rationals. We leave the latter construction to the future, and discuss the construction of rationals here.

**Example 1.22** (Construction of  $\mathbb{Q}$  from  $\mathbb{Z}$ ). Define a relation on  $\mathbb{Z} \times \mathbb{Z}^\times$  (where  $\mathbb{Z}^\times = \mathbb{Z} \setminus \{0\}$ ) as follows. If  $(a, b), (a', b') \in \mathbb{Z} \times \mathbb{Z}^\times$ , we say  $(a, b) \sim (a', b')$  iff  $ab' = a'b$ . It is a routine check that  $\sim$  is an equivalence relation. Let  $\mathbb{Q} = (\mathbb{Z} \times \mathbb{Z}^\times) / \sim$ , and write the equivalence class of  $(a, b)$  as  $a/b$  or  $\frac{a}{b}$ . Define additions and multiplications in  $\mathbb{Q}$  to be

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd} \quad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}$$

We leave it to the readers to check that this definition is **well-defined**: If  $(a, b) \sim (a', b')$  and  $(c, d) \sim (c', d')$  then  $(ad + bc, bd) \sim (a'd' + b'c', b'd')$  and  $(ac, bd) \sim (a'c', b'd')$ .

We regard  $\mathbb{Z}$  as a subset of  $\mathbb{Q}$  by identifying  $n \in \mathbb{Z}$  with  $\frac{n}{1}$ . (This is possible since the map  $n \in \mathbb{Z} \mapsto \frac{n}{1} \in \mathbb{Q}$  is injective.) Each  $a/b \in \mathbb{Q}$  has additive inverse  $\frac{-a}{b}$ . If  $a/b \in \mathbb{Q}$  is not zero (i.e.  $(a, b) \not\sim (0, 1)$ ), then  $a/b$  has multiplicative inverse  $b/a$ . This makes  $\mathbb{Q}$  a field: the field of **rational numbers**.

If  $a/b \in \mathbb{Q}$ , we say  $a/b \geq 0$  if  $ab \geq 0$ . Check that this is well-defined (i.e., if  $(a, b) \sim (a', b')$ , then  $ab \geq 0$  iff  $a'b' \geq 0$ ). More generally, if  $a/b, c/d \in \mathbb{Q}$ , we say  $\frac{a}{b} \geq \frac{c}{d}$  if  $\frac{a}{b} - \frac{c}{d} \geq 0$ . Check that  $\geq$  is a total order on  $\mathbb{Q}$ . Check that  $\mathbb{Q}$  is an Archimedean ordered field, defined below.  $\square$

**Definition 1.23.** A field  $\mathbb{F}$ , together with a total order  $\leq$ , is called an **ordered field**, if for every  $a, b, c \in \mathbb{F}$  we have

- (Addition preserves  $\leq$ ) If  $a \leq b$  then  $a + c \leq b + c$ .
- (Multiplication by  $\mathbb{F}_{\geq 0}$  preserves  $\geq 0$ ) If  $a, b \geq 0$  then  $ab \geq 0$ .

These two properties relate  $\leq$  to  $+$  and  $\cdot$  respectively.

**Remark 1.24.** Many familiar properties about inequalities in  $\mathbb{Q}$  hold for an ordered field. For instance:

$$\begin{aligned}
 a \geq b \wedge c \geq d &\implies a + c \geq b + d \\
 a \geq 0 &\iff -a \leq 0 \\
 a \geq 0 \wedge b \geq c &\iff ab \geq ac \\
 a \leq 0 \wedge b \geq c &\iff ab \leq a \\
 &a^2 \geq 0 \\
 0 < a \leq b &\implies 0 < b^{-1} \leq a^{-1}
 \end{aligned}$$

Check them yourself, or see [Rud-P, Prop. 1.18].

**Definition 1.25.** We say that an ordered field  $\mathbb{F}$  satisfies **Archimedean property** if for each  $a, b \in \mathbb{F}$  we have

$$a > 0 \implies \exists n \in \mathbb{N} \text{ such that } na > b$$

where  $na$  means  $\underbrace{a + \cdots + a}_n$ .

**Example 1.26.**  $\mathbb{Q}$  satisfies Archimedean property. Indeed, let  $a, b \in \mathbb{Q}$  and  $a > 0$ . Then  $a = p/q$  and  $b = r/s$  where  $p, q, s \in \mathbb{Z}_+$  and  $r \in \mathbb{Z}$ . So  $na > b$  where  $n = q|r| + q$ .

Prop. 1.29 gives an important application of Archimedean property. We will use this in the construction of  $\mathbb{R}$  from  $\mathbb{Q}$ , and in the proof that  $\mathbb{Q}$  is dense in  $\mathbb{R}$ .

**Definition 1.27.** Let  $\mathbb{F}$  be a field. A subset  $\mathbb{E} \subset \mathbb{F}$  is called a **subfield** of  $\mathbb{F}$ , if  $\mathbb{E}$  contains the 1 of  $\mathbb{F}$ , and if  $\mathbb{E}$  is closed under the operations of addition, multiplication, taking negative, and taking inverse in  $\mathbb{F}$  (i.e. if  $a, b \in \mathbb{E}$  then  $a + b, ab, -a \in \mathbb{E}$ , and  $a^{-1} \in \mathbb{E}$  whenever  $a \neq 0$ ). We also call  $\mathbb{F}$  a **field extension** of  $\mathbb{E}$ , since  $\mathbb{E}$  is clearly a field.

Note that if  $\mathbb{E}$  is a subfield of  $\mathbb{F}$ , the 0 of  $\mathbb{F}$  is in  $\mathbb{E}$  since  $0 = 1 + (-1) \in \mathbb{E}$ .

**Definition 1.28.** Let  $\mathbb{E}$  be an ordered field. A field extension  $\mathbb{F}$  of  $\mathbb{E}$  is called an **ordered field extension**, if  $\mathbb{F}$  is equipped with a total order  $\leq$  such that  $\mathbb{F}$  is an ordered field, and if the order  $\leq$  of  $\mathbb{F}$  restricts to that of  $\mathbb{E}$ . We also call  $\mathbb{E}$  an **ordered subfield** of  $\mathbb{F}$ .

Our typical example of ordered field extension will be  $\mathbb{Q} \subset \mathbb{R}$ .

**Proposition 1.29.** Let  $\mathbb{F}$  be an ordered field extension of  $\mathbb{Q}$ . Assume that  $\mathbb{F}$  is Archimedean. Then for every  $x, y \in \mathbb{F}$  satisfying  $x < y$ , there exists  $p \in \mathbb{Q}$  such that  $x < p < y$ .

*Proof.* Assume  $x, y \in \mathbb{F}$  and  $x < y$ . Then  $y - x > 0$  (since  $y - x \neq 0$  and  $-x + x \leq -x + y$ ). By Archimedean property, there exists  $n \in \mathbb{Z}_+$  such that  $n(y - x) > 1$ . So  $y - x > \frac{1}{n}$  and hence  $x + \frac{1}{n} < y$ .

Let us prove that the subset

$$A = \left\{ k \in \mathbb{Z} : \frac{k}{n} \leq x \right\}$$

is nonempty and bounded from above in  $\mathbb{Z}$ . By Archimedean property, there is  $m \in \mathbb{Z}_+$  such that  $m > nx$ , i.e.  $\frac{m}{n} > x$ . So for each  $k \in \mathbb{Z}_+$  satisfying  $k \geq m$ , we have  $\frac{k}{n} = \frac{m}{n} + \frac{k-m}{n} > x$ . Therefore, for each  $k \in A$  we have  $k < m$ . So  $A$  is bounded above. By Archimedean property again, there is  $l \in \mathbb{Z}_+$  such that  $\frac{l}{n} > -x$ . So  $-\frac{l}{n} < x$ , and hence  $A$  is nonempty.

We now use the fact that every nonempty subset of  $\mathbb{Z}$  bounded above has a maximal element. Let  $k = \max A$ . Since  $k + 1 \notin A$ , we have  $x < \frac{k+1}{n}$ . Since  $\frac{k}{n} \leq x$ , we have

$$\frac{k+1}{n} = \frac{k}{n} + \frac{1}{n} \leq x + \frac{1}{n} < y$$

This proves  $x < p < y$  with  $p = \frac{k+1}{n}$ . □

To introduce  $\mathbb{R}$  formally, we need more definitions:

**Definition 1.30.** Let  $(X, \leq)$  be a poset and  $E \subset X$ . An **upper bound of  $E$  in  $X$**  is an element  $x \in X$  satisfying  $e \leq x$  for all  $e \in E$ . An upper bound  $x \in X$  of  $E$  is called a **least upper bound** or a **supremum** if  $x \leq y$  for every upper bound  $y \in Y$  of  $E$ . In this case, we write the supremum as  $\sup E$ . It is not hard to check that supremums are unique if they exist.

We leave it to the readers to define **lower bounds** and the **greatest lower bound** (if exists) of  $E$ , also called the **infimum** and is denoted by  $\inf E$ . □

**Definition 1.31.** Let  $(X, \leq)$  be a poset. We say that  $X$  satisfies the **least-upper-bound property**, if every every nonempty subset  $E \subset X$  which is bounded above (i.e.  $E$  has an upper bound) has a supremum in  $X$ . The **greatest-lower-bound property** is defined in the opposite way.

**Example 1.32.**  $\mathbb{Z}$  satisfies the least-upper-bound and the greatest-lower-bound property: Let  $A \subset \mathbb{Z}$ . If  $A$  is bounded above (resp. below), then the maximum  $\max A$  (resp. minimum  $\min A$ ) exists and is the supremum (resp. infimum) of  $A$ .

**Example 1.33.** Let  $X$  be a set. Then  $(2^X, \subset)$  satisfies the least-upper-bound and the greatest-lower-bound property: Let  $\mathcal{A} \subset 2^X$ , i.e.,  $\mathcal{A}$  is a set of subsets of  $X$ . Then  $\mathcal{A}$  is bounded from above by  $X$ , and is bounded from below by  $\emptyset$ . Moreover,

$$\sup \mathcal{A} = \bigcup_{A \in \mathcal{A}} A \quad \inf \mathcal{A} = \bigcap_{A \in \mathcal{A}} A$$

**Theorem 1.34.** *There is an ordered field extension of  $\mathbb{Q}$  which is Archimedean and satisfies the least-upper-bound property. This field is denoted by  $\mathbb{R}$ . Its elements are called **real numbers**.*

Thm. 1.34 will be proved in Ch. 6. Note that by taking negative, we see that  $\mathbb{R}$  also satisfies the greatest-lower-bound property.

**Remark 1.35.** The ordered field extensions satisfying the conditions in Thm. 1.34 are unique “up to isomorphisms”. (The words “**isomorphism**” and “equivalence” are often interchangeable, though “isomorphism” is more often used in the algebraic setting, whereas “equivalence” can be used in almost every context. For example, in point-set topology, “equivalence” means “homeomorphism”.) We leave it to the readers to give the precise statement. We will not use this uniqueness in this course.

Note that to compare two extensions  $\mathbb{F}, \mathbb{R}$  of  $\mathbb{Q}$ , it is very confusing to regard  $\mathbb{Q}$  as a subset of both  $\mathbb{F}$  and  $\mathbb{R}$ . You’d better consider two different injective maps  $\tau : \mathbb{Q} \rightarrow \mathbb{F}$  and  $\iota : \mathbb{Q} \rightarrow \mathbb{R}$  preserving the algebraic operations and the order of  $\mathbb{Q}$ , and use a commutative diagram to indicate that  $\tau$  and  $\iota$  are equivalent. (Thus, what’s happening here is that we have an equivalence of maps, not just an equivalence of the fields  $\mathbb{F}$  and  $\mathbb{R}$ .)  $\square$

**Definition 1.36.** Let  $-\infty, +\infty$  be two different symbols, and extend the total order  $\leq$  of  $\mathbb{R}$  to the **extended real line**

$$\overline{\mathbb{R}} = \mathbb{R} \cup \{-\infty, +\infty\}$$

by letting  $-\infty < x < +\infty$  for all  $x \in \mathbb{R}$ . Define for each  $x \in \mathbb{R}$  that

$$\begin{aligned} x \pm \infty &= \pm\infty + x = \pm\infty & +\infty - (-\infty) &= +\infty \\ x \cdot (\pm\infty) &= \pm\infty \cdot x = \begin{cases} \pm\infty & \text{if } x > 0 \\ \mp\infty & \text{if } x < 0 \end{cases} \\ \frac{x}{\pm\infty} &= 0 \\ \frac{\pm\infty}{x} &= x^{-1} \cdot (\pm\infty) \quad \text{if } x \neq 0 \end{aligned}$$

If  $a, b \in \overline{\mathbb{R}}$  and  $a \leq b$ , we define **intervals** with endpoints  $a, b$ :

$$\begin{aligned} [a, b] &= \{x \in \overline{\mathbb{R}} : a \leq x \leq b\} & (a, b) &= \{x \in \overline{\mathbb{R}} : a < x < b\} \\ (a, b] &= \{x \in \overline{\mathbb{R}} : a < x \leq b\} & [a, b) &= \{x \in \overline{\mathbb{R}} : a \leq x < b\} \end{aligned} \tag{1.9}$$

So  $\mathbb{R} = (-\infty, +\infty)$  and  $\overline{\mathbb{R}} = [-\infty, +\infty]$ . If  $a, b$  are in  $\mathbb{R}$ , we say that the corresponding interval is **bounded**.

In this course, unless otherwise stated, an interval always means one of the four sets in (1.9). The first two intervals are called respectively a **closed interval** and an **open interval**.

**Remark 1.37.** Clearly, every subset  $E$  of  $\overline{\mathbb{R}}$  is bounded and has a supremum and an infimum. We have that  $\sup E = +\infty$  iff  $E$  is not bounded above in  $\mathbb{R}$ , and that  $\inf E = -\infty$  iff  $E$  is not bounded below in  $\mathbb{R}$ .

## 1.4 Cardinalities, countable sets, and product spaces $Y^X$

**Definition 1.38.** Let  $A$  and  $B$  be sets. We say that  $A$  and  $B$  have the same **cardinality** and write  $\text{card}(A) = \text{card}(B)$  (or simply  $A \approx B$ ), if there is a bijection  $f : A \rightarrow B$ . We write  $\text{card}(A) \leq \text{card}(B)$  (or simply  $A \lesssim B$ ) if  $A$  and a subset of  $B$  have the same cardinality.

**Exercise 1.39.** Show that  $\text{card}(A) \leq \text{card}(B)$  iff there is an injection  $f : A \rightarrow B$ , iff there is a surjection  $g : B \rightarrow A$ . (You need either Axiom of Choice or its consequence (1.6b) to prove the last equivalence.)

It is clear that  $\approx$  is an equivalence relation on the collection of sets. It is also true that  $\lesssim$  is a partial order: Reflexivity and transitivity are easy to show. The proof of antisymmetry is more involved:

**Theorem 1.40 (Schröder-Bernstein).** *Let  $A, B$  be two sets. If  $A \lesssim B$  and  $B \lesssim A$ , then  $A \approx B$ .*

★★ *Proof.* Assume WLOG that  $A \subset B$ . Let  $f : B \rightarrow A$  be an injection. Let  $A_n = f^n(A)$  defined inductively by  $f^0(A) = A$ ,  $f^n(A) = f(f^{n-1}(A))$ . Let  $B_n = f^n(B)$ . Then

$$B_0 \supset A_0 \supset \cdots \supset B_n \supset A_n \supset B_{n+1} \supset \cdots$$

In particular,  $C = \bigcap_{n \in \mathbb{N}} A_n$  equals  $\bigcap_{n \in \mathbb{N}} B_n$ . Note that  $f$  gives a bijection  $B_n \setminus A_n \rightarrow B_{n+1} \setminus A_{n+1}$  (since  $f$  gives bijections  $B_n \rightarrow B_{n+1}$  and  $A_n \rightarrow A_{n+1}$ ). Therefore, we have a bijection  $g : B \rightarrow A$  defined by

$$g(x) = \begin{cases} f(x) & \text{if } x \in B_n \setminus A_n \text{ for some } n \in \mathbb{N} \\ x & \text{otherwise} \end{cases}$$

where “otherwise” means either  $x \in C$  or  $x \in A_n \setminus B_{n+1}$  for some  $n$ . □

Intuition about the above proof: View  $B$  as an onion. The layers of  $B$  are  $B_n \setminus A_n$  (the odd layers) and  $A_n \setminus B_{n+1}$  (the even layers). The bijection  $g$  maps each odder layer to the subsequent odd one, and fixes the even layers and the core  $C$ .

**Example 1.41.** If  $-\infty < a < b < +\infty$ , then  $(0, 1) \approx (a, b)$ .

*Proof.*  $f : (0, 1) \rightarrow (a, b)$  sending  $x$  to  $(b - a)x + a$  is a bijection.  $\square$

**Example 1.42.** If  $-\infty < a < b < +\infty$ , then  $\mathbb{R} \approx (a, b)$

*Proof.* By the previous example, it suffices to prove  $\mathbb{R} \approx (-1, 1)$ . The function

$$f : \mathbb{R} \rightarrow (-1, 1) \quad f(x) = \begin{cases} \frac{x}{1+x} & \text{if } x \geq 0 \\ -f(-x) & \text{if } x < 0 \end{cases} \quad (1.10)$$

is bijective.  $\square$

Alternatively, one may use the tangent function to give a bijection between  $(-\pi/2, \pi/2)$  and  $\mathbb{R}$ . I have avoided this method, since (1.10) is more elementary than trigonometric functions. The mathematically rigorous definition of trigonometric functions and the verification of their well-known properties are far from easy tasks.

**Proposition 1.43.** Let  $I$  be an interval with endpoints  $a < b$  in  $\overline{\mathbb{R}}$ . Then  $I \approx \mathbb{R}$ .

*Proof.* Let  $A = (0, 1) \cup \{-\infty, +\infty\}$ . By Exp. 1.42, we have

$$(a, b) \subset I \lesssim \overline{\mathbb{R}} \approx A \approx [0, 1] \subset (-2, 2) \approx (a, b)$$

So  $I \approx \overline{\mathbb{R}}$  by Schröder-Bernstein Thm. 1.40. In particular,  $\mathbb{R} = (-\infty, +\infty) \approx \overline{\mathbb{R}}$ .  $\square$

**Definition 1.44.** A set  $A$  is called **finite** if  $A \lesssim \{1, \dots, n\}$  for some  $n \in \mathbb{Z}_+$ .  $A$  is called **countable** if  $A \lesssim \mathbb{N}$ .

Clearly, a set  $A$  is finite iff either  $A \approx \emptyset$  or  $A \approx \{1, \dots, n\}$  for some  $n \in \mathbb{Z}_+$ .

**Remark 1.45.** Let  $A \subset \mathbb{N}$ . If  $A$  is bounded above, then  $A \subset \{0, \dots, n\}$  and hence  $A$  is finite. If  $A$  is not bounded above, then we can construct a strictly increasing sequence  $(x_n)_{n \in \mathbb{N}}$  in  $A$ . (Pick any  $x_0 \in A$ . Suppose we have  $x_n \in A$ . Since  $x_n$  is not an upper bound of  $A$ , there is  $x_{n+1} \in A$  larger than  $x_n$ . So  $(x_n)_{n \in \mathbb{N}}$  can be constructed inductively.) This gives an injection  $\mathbb{N} \rightarrow A$ . Therefore  $A \gtrsim \mathbb{N}$ , and hence  $A \approx \mathbb{N}$  by Schröder-Bernstein.

It follows that if  $B \lesssim \mathbb{N}$ , then either  $B$  is a finite set, or  $B \approx \mathbb{N}$ . Therefore, “a set  $B$  is **countably infinite**” means the same as “ $B \approx \mathbb{N}$ ”.  $\square$

**Theorem 1.46.** A countable union of countable sets is countable. In particular,  $\mathbb{N} \times \mathbb{N} \approx \mathbb{N}$ .

*Proof.* Recall Exe. 1.39. Let  $A_1, A_2, \dots$  be countable sets. Since each  $A_i$  is countable, there is a surjection  $f_i : \mathbb{N} \rightarrow A_i$ . Thus, the map  $f : \mathbb{N} \times \mathbb{N} \rightarrow \bigcup_i A_i$  defined by  $f(i, j) = f_i(j)$  is surjective. Therefore, it suffices to show that there is a surjection  $\mathbb{N} \rightarrow \mathbb{N} \times \mathbb{N}$ . This is true, since we have a bijection  $g : \mathbb{N} \rightarrow \mathbb{N} \times \mathbb{N}$  where  $g(0), g(1), g(2), \dots$  are  $(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2), (3, 0), (2, 1), (1, 2), (0, 3), \dots$ , as shown by the figure

□

As an application, we prove the extremely important fact that  $\mathbb{Q}$  is countable.

**Corollary 1.47.** *We have  $\mathbb{N} \approx \mathbb{Z}_+ \approx \mathbb{Z} \approx \mathbb{Q}$ .*

*Proof.* Clearly  $\mathbb{Z}_{<0} \approx \mathbb{N} \approx \mathbb{Z}_+$ . By Thm. 1.46,  $\mathbb{Z} = \mathbb{Z}_{<0} \cup \mathbb{N}$  is countably infinite, and hence  $\mathbb{Z} \approx \mathbb{N}$ . It remains to prove  $\mathbb{Z} \approx \mathbb{Q}$ . By Schröder-Bernstein, it suffices to prove  $\mathbb{Q} \lesssim \mathbb{Z}$ . By Thm. 1.46 again,  $\mathbb{Z} \times \mathbb{Z} \approx \mathbb{Z}$ . By Exp. 1.22, there is a surjection from a subset of  $\mathbb{Z} \times \mathbb{Z}$  to  $\mathbb{Q}$ . So  $\mathbb{Q} \lesssim \mathbb{Z} \times \mathbb{Z} \approx \mathbb{Z}$ . □

Later, when we have learned Zorn's Lemma (an equivalent form of Axiom of Choice), we will be able to prove the following generalization of  $\mathbb{N} \times \mathbb{N} \approx \mathbb{N}$ . So we defer the proof of the following theorem to a later section.

**Theorem 1.48.** *Let  $X$  be a infinite set. Then  $X \times \mathbb{N} \approx X$ .*

Our next goal is to prove an exponential law  $a^{b+c} = a^b \cdot a^c$  for cardinalities. For that purpose, we first need to define the set-theoretic operations that correspond to the summation  $b + c$  and the exponential  $a^b$ .

**Definition 1.49.** We write  $X = \bigsqcup_{\alpha \in \mathcal{A}} A_\alpha$  and call  $X$  the **disjoint union** of  $(A_\alpha)_{\alpha \in \mathcal{A}}$ , if  $X = \bigcup_{\alpha \in \mathcal{A}} A_\alpha$  and  $(A_\alpha)_{\alpha \in \mathcal{A}}$  is a family of pairwise disjoint sets (i.e.  $A_\alpha \cap A_\beta = \emptyset$  if  $\alpha \neq \beta$ ). If moreover  $\mathcal{A} = \{1, \dots, n\}$ , we write  $X = A_1 \sqcup \dots \sqcup A_n$ .

**Definition 1.50.** Let  $X, Y$  be sets. Then

$$Y^X = \{\text{functions } f : X \rightarrow Y\} \quad (1.11)$$

A more precise definition of  $Y^X$  (in the spirit of (1.4)) is  $\{f \in X \times Y \mid f : X \rightarrow Y \text{ is a function}\}$ . Note that by Rem. 1.7,

$$Y^\emptyset = \{\emptyset\} \quad (1.12)$$

This new notation is compatible with the old one  $Y^n = Y \times \cdots \times Y$ :

**Example 1.51.** Let  $n \in \mathbb{Z}_+$ . We have  $Y^{\{1, \dots, n\}} \approx Y^n$  due to the bijection

$$Y^{\{1, \dots, n\}} \rightarrow Y^n \quad f \mapsto (f(1), \dots, f(n))$$

**Remark 1.52.** The above example suggests that in the general case that  $X$  is not necessarily finite, we can view each function  $f : X \rightarrow Y$  as  $(f(x))_{x \in X}$ , an **indexed family of elements** of  $Y$  with index set  $X$ . Thus, intuitively and hence not quite rigorously,

$$Y^X = \underbrace{Y \times Y \times \cdots}_{\text{card}(X) \text{ pieces}} \quad (1.13)$$

This generalizes the intuition in Def. 1.8 that a function  $f : \mathbb{Z}_+ \rightarrow Y$  is equivalently a sequence  $(f(1), f(2), f(3), \dots)$ .

The viewpoint that  $Y^X$  is a **product space** with index set  $X$  is very important and will be adopted frequently in this course. More generally, we can define:  $\square$

**Definition 1.53.** Let  $(X_i)_{i \in I}$  be a family of sets with index set  $I$ . Their **product space** is defined by

$$\prod_{i \in I} X_i = \{f \in \mathfrak{X}^I : f(i) \in X_i \text{ for all } i \in I\}$$

where  $\mathfrak{X} = \bigcup_{i \in I} X_i$ . If each  $X_i$  is nonempty, then  $\prod_{i \in I} X_i$  is nonempty by Axiom of Choice. An element of  $\prod_{i \in I} X_i$  is also written as  $(f_i)_{i \in I}$  when the  $i$ -th component of it is  $f_i \in X_i$ .

In particular, if all  $X_i$  are equal to  $X$ , then  $X^I = \prod_{i \in I} X$ .

**Example 1.54.** Let  $X$  be a set. For each  $A \subset X$ , define the **characteristic function**  $\chi_A : X \rightarrow \{0, 1\}$  to be

$$\chi_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A \end{cases}$$

Then we have

$$2^X \approx \{0, 1\}^X$$

since the following map is bijective:

$$2^X \rightarrow \{0, 1\}^X \quad A \mapsto \chi_A$$

Its inverse is  $f \in \{0, 1\}^X \mapsto f^{-1}(1) \in 2^X$ .

**Proposition 1.55** (Exponential Law). *Suppose that  $X = A_1 \sqcup \cdots \sqcup A_n$ . Then*

$$Y^X \approx Y^{A_1} \times \cdots \times Y^{A_n}$$

*Proof.* We have a bijection

$$\begin{aligned} \Phi : Y^X &\rightarrow Y^{A_1} \times \cdots \times Y^{A_n} \\ f &\mapsto (f|_{A_1}, \dots, f|_{A_n}) \end{aligned} \tag{1.14}$$

where we recall that  $f|_{A_i}$  is the restriction of  $f$  to  $A_i$ . □

**Exercise 1.56.** Assume that  $A_1, \dots, A_n$  are subsets of  $X$ . Define  $\Phi$  by (1.14). Prove that  $\Phi$  is injective iff  $X = A_1 \cup \cdots \cup A_n$ . Prove that  $\Phi$  is surjective iff  $A_1, \dots, A_n$  are pairwise disjoint.

**Corollary 1.57.** *Let  $X, Y$  be finite sets with cardinalities  $m, n \in \mathbb{N}$  respectively. Assume that  $Y \neq \emptyset$ . Then  $Y^X$  is a finite set with cardinality  $n^m$ .*

*Proof.* The special case that  $m = 0$  (i.e.  $X = \emptyset$ , cf. (1.12)) and  $m = 1$  is clear. When  $m > 1$ , assume WLOG that  $X = \{1, \dots, m\}$ . Then  $X = \{1\} \sqcup \cdots \sqcup \{m\}$ . Apply Prop. 1.55 to this disjoint union. We see that  $Y^X \simeq Y \times \cdots \times Y \simeq \{1, \dots, n\}^m$  has  $n^m$  elements. □

We end this section with some (in)equalities about the cardinalities of product spaces. To begin with, we write  $X \lesssim Y$  (or  $\text{card}(X) < \text{card}(Y)$ ) if  $X \lesssim Y$  and  $X \not\approx Y$ .

**Proposition 1.58.** *Let  $X, Y$  be sets with  $\text{card}(Y) \geq 2$  (i.e.  $Y$  has at least two elements). Then  $X \lesssim Y^X$ . In particular,  $X \lesssim 2^X$ .*

*Proof.* The case  $X = \emptyset$  is obvious since  $0 < 1$ . So we assume  $Y \neq \emptyset$ . Clearly  $2^X \simeq \{0, 1\}^X$  is  $\lesssim Y^X$ . So it suffices to prove  $X \lesssim 2^X$ . Since the map  $X \rightarrow 2^X$  sending  $x$  to  $\{x\}$  is injective,  $X \lesssim 2^X$ . Let us prove  $X \not\approx 2^X$ .

Assume that  $X \approx 2^X$ . So there is a bijection  $\Phi : X \rightarrow 2^X$  sending each  $x \in X$  to a subset  $\Phi(x)$  of  $X$ . Motivated by Russell's Paradox (1.3), we define

$$S = \{x \in X : x \notin \Phi(x)\}$$

Since  $\Phi$  is surjective, there exists  $y \in X$  such that  $S = \Phi(y)$ . If  $y \in \Phi(y)$ , then  $y \in S$ , and hence  $y \notin \Phi(y)$  by the definition of  $S$ . If  $y \notin \Phi(y)$ , then  $y \notin S$ , and hence  $y \in \Phi(y)$  by the definition of  $S$ . This gives a contradiction. □

**Remark 1.59.** Write  $\{1, \dots, n\}^X$  as  $n^X$  for short. Assuming that real numbers have decimal, binary, or (more generally) base- $n$  representations where  $n \in \mathbb{Z}_{\geq 2}$ , then  $\mathbb{R} \approx n^{\mathbb{N}}$ . So by Prop. 1.58,  $\mathbb{N} \lesssim \mathbb{R}$ , i.e.  $\mathbb{R}$  is uncountable. The base- $n$  representations of real numbers suggest that  $\text{card}(n^{\mathbb{N}})$  is independent of  $n$ . This fact can be proved by elementary methods without resorting to the analysis of real numbers:

**Theorem 1.60.** *Let  $X$  be an infinite set. Then*

$$2^X \approx 3^X \approx 4^X \approx \dots \approx \mathbb{N}^X$$

*Proof.* First, we assume that  $X = \mathbb{N}$ . Clearly, for each  $n \in \mathbb{Z}_{\geq 2}$  we have  $2^X \lesssim n^X \lesssim \mathbb{N}^X$ . Since elements of  $\mathbb{N}^X$  are subsets of  $X \times \mathbb{N}$  (i.e. elements of  $2^{X \times \mathbb{N}}$ ), we have

$$\mathbb{N}^X \subset 2^{X \times \mathbb{N}} \simeq 2^X$$

since  $X \times \mathbb{N} \approx X$  by Thm. 1.46. So  $2^X \approx n^X \approx \mathbb{N}^X$  by Schröder-Bernstein.

As pointed out earlier (cf. Thm. 1.48), it can be proved by Zorn's Lemma that  $X \times \mathbb{N} \approx X$  for every infinite set  $X$ . So the same conclusion holds for such  $X$ .  $\square$

## 2 Metric spaces

We first give an informal introduction to metric spaces, hoping to motivate the readers from a (relatively) historical perspective. It is okay if you do not understand all of the concepts mentioned in the introduction on the first read. Simply return to this section when you feel unmotivated while formally studying these concepts in later sections. (The same suggestion applies to all the introductory sections and historical comments in our notes.)

### 2.1 Introduction: what is point-set topology?

The method which has been used with success by Volterra and Hilbert consists in observing that a function (for instance a continuous one) can be replaced by a countable infinity of parameters. One treats the problem first as though one had only a finite number of parameters and then one goes to the limit... We believe that this method has played a useful role because it followed intuition, but that its time has passed... The most fruitful method in functional analysis seems to us to treat the element of which the functional depends directly as a variable and in the form in which it presents itself naturally.

— Fréchet, 1925 (cf. [Jah, Sec. 13.8])

In this chapter, we begin the study of point-set topology by learning one of its most important notions: metric spaces. Similar to [Rud-P], we prefer to introduce metric spaces and basic point-set topology at the early stage of our study. An obvious reason for doing so is that metric spaces provide a uniform language for the study of basic analysis problems in  $\mathbb{R}, \mathbb{R}^n, \mathbb{C}^n$ , and more generally in function spaces such as the space of continuous functions  $C([a, b])$  on the interval  $[a, b] \subset \mathbb{R}$ . With the help of such a language, for example, many useful criteria for the convergence of series in  $\mathbb{R}$  and  $\mathbb{C}$  (e.g. root test, ratio test) are generalized straightforwardly to criteria for the *uniform* convergence of series of functions in  $C([a, b])$ .

Point-set topology was born in 1906 when Fréchet defined metric spaces, motivated mainly by the study of function spaces in analysis (i.e. *functional analysis*). Indeed, point-set topology and functional analysis are the two faces of the same coin: they both originated from the study of **functionals**, i.e., functions of functions. See for example (2.1). The core ideas of point-set topology are as follows:

- (1) Take  $X$  to be a set of functions defined on a “classical space” (e.g. the set of all continuous functions  $f : [a, b] \rightarrow \mathbb{C}$ ). Then a functional is a function  $S : X \rightarrow \mathbb{C}$ . This is a generalization of functions on  $\mathbb{R}, \mathbb{C}, \mathbb{R}^n, \mathbb{C}^n$  or on their subsets.

- (2) Unlike  $\mathbb{R}^n$ , a function space  $X$  is usually “infinite dimensional”. Thus, one may think that a functional  $S$  is a function with infinite variables. In point-set topology, this viewpoint is abandoned; the philosophy of point-set topology is diametrically opposed to that of multivariable calculus.<sup>3</sup> Instead, one should view a functional  $S$  as a function with one variable  $x$ , where  $x$  denotes a general point of the function space  $X$ .
- (3) Rather than looking at each variable/component and doing explicit multivariable calculations, one uses geometric intuitions to study the analytic properties of functionals.<sup>4</sup> These geometric intuitions (e.g. distances, open balls, convergence) are borrowed from  $\mathbb{R}$  and  $\mathbb{R}^n$  and are mostly irrelevant to dimensions or numbers of variables.

(Sequential) **compactness**, **completeness**, and **separability** are prominent geometric properties that are useful in the study of the analytic properties of functionals. The importance of these three notions was already recognized by Fréchet by the time he defined metric spaces. The study of these three properties will be a main theme of our course.

Consider sequential compactness for example. The application of compactness to function spaces originated from the problems in calculus of variations. For instance, let  $L(x, y, z)$  be a polynomial or (more generally) a continuous function in 3 variables. We want to find a “good” (e.g. differentiable) function  $f : [0, 1] \rightarrow \mathbb{R}$  minimizing or maximizing the expression

$$S(f) = \int_0^1 L(t, f(t), f'(t)) dt \quad (2.1a)$$

This is the general setting of Lagrangian mechanics. In the theory of integral equations, one considers the extreme values and points of the functional

$$S(f) = \int_0^1 \int_0^1 f(x) K(x, y) \overline{f(y)} dx dy \quad (2.1b)$$

where  $K : [0, 1]^2 \rightarrow \mathbb{R}$  is continuous and  $f : [0, 1] \rightarrow \mathbb{C}$  is subject to the condition  $\int_0^1 |f(x)|^2 dx \leq 1$ . Any  $f$  maximizing (resp. minimizing)  $S(f)$  is an eigenvector of the linear operator  $g \mapsto \int_0^1 K(x, y) g(y) dy$  with maximal (resp. minimal) eigenvalue.

As we shall learn, (sequential) compactness is closely related to the problem of finding (or proving the existence of) maximal/minimal values of a continuous

---

<sup>3</sup>Very often, the formula of  $S(f)$  involves an integral. See e.g. (2.1). Mathematicians (e.g. Volterra, Lévy, Fredholm, and early Hilbert) used to study  $S(f)$  by discretizing  $S(f)$ , i.e., by approximating integrals by finite sums. Thus,  $S$  is approximated by a sequence of functions with  $n$  variables where  $n \rightarrow \infty$ . This viewpoint is abandoned in point-set topology.

<sup>4</sup>This is similar to linear algebra where one prefers vectors, linear subspaces, and linear operators to  $n$ -tuples, sets of solutions, and matrices.

function and the points at which the function attains its maximum/minimum. So, in 19th century, when people were already familiar with sequential compactness in  $\mathbb{R}^n$  (e.g. Bolzano-Weierstrass theorem, Heine-Borel theorem), they applied compactness to function spaces and functionals. The idea is simple: Suppose we are given  $X$ , a set of functions (say continuous and differentiable) from  $[a, b]$  to  $\mathbb{R}$ . We want to find  $f \in X$  maximizing  $S(f)$ . Here is an explicit process (see also the proof of Lem. 3.2):

- (A) Find a sequence  $(f_n)_{n \in \mathbb{Z}_+}$  in  $X$  such that  $S(f_n)$  increases to  $M = \sup S(X)$ .
- (B) Define convergence in  $X$  in a suitable way, and verify that  $S : X \rightarrow \mathbb{R}$  is continuous (i.e. if  $f_n$  converges to  $f$  in the way we define, then  $S(f_n) \rightarrow S(f)$ ).
- (C) Suppose we can find a subsequence  $(f_{n_k})_{k \in \mathbb{Z}_+}$  converging to some  $f \in X$ , then  $S$  attains its maximum at  $f$ . In particular,  $S(f) = M$  and hence  $M < +\infty$ .

To carry out step (B), we need to define suitable geometric structures for a function space  $X$  so that the convergence of sequences in  $X$  and the continuity of functions  $S : X \rightarrow \mathbb{R}$  can be defined and studied in a similar pattern as that for  $\mathbb{R}^n$ . **Metric** (of a metric space) and **topology** (of a topological space) are such geometric structures. As we shall learn, the topology of a metric space is uniquely determined by the convergence of sequences in this space.

Step (C) can be carried out if every sequence in  $X$  has a convergent subsequence, i.e., if  $X$  is sequentially compact. Thus, we need a good criterion for sequential compactness for subsets of a function space. Arzelà-Ascoli theorem, the  $C([a, b])$ -version of Heine-Borel theorem, is such a criterion. This famous theorem was proved in late 19th century (and hence before the birth of point-set topology), and it gave an important motivation for Fréchet to consider metric spaces in general. We will learn this theorem at the end of the first semester.

To summarize: Metric spaces are defined not just for fun. We introduce such geometric objects because we want to study the convergence of sequences and the analytic properties of continuous functions using geometric intuitions. And moreover, the examples we are interested in are not just subsets of  $\mathbb{R}^n$ , but also subsets of function spaces. With this in mind, we now begin our journey into point-set topology.

## 2.2 Basic definitions and examples

**Definition 2.1.** Let  $X$  be a set. A function  $d : X \times X \rightarrow \mathbb{R}_{\geq 0}$  is called a **metric** if for all  $x, y, z \in X$  we have

$$(1) \quad d(x, y) = d(y, x).$$

(2)  $d(x, y) = 0$  iff  $x = y$ .

(3) (Triangle inequality)  $d(x, z) \leq d(x, y) + d(y, z)$ .

The pair  $(X, d)$ , or simply  $X$ , is called a **metric space**. If  $x \in X$  and  $r \in (0, +\infty]$ ,<sup>5</sup> the set

$$B_X(x, r) = \{y \in X : d(x, y) < r\}$$

often abbreviated to  $B(x, r)$ , is called the **open ball** with center  $x$  and radius  $r$ . If  $r \in [0, +\infty)$ ,

$$\overline{B}_X(x, r) = \{y \in X : d(x, y) \leq r\}$$

also abbreviated to  $\overline{B}(x, r)$ , is called the **closed ball** with center  $x$  and radius  $r$ .

We make some comments on this definition.

**Remark 2.2.** That “ $d(x, y) = 0$  iff  $x = y$ ” is very useful. Think about  $X$  as a set of functions  $[0, 1] \rightarrow \mathbb{R}$  and  $d$  is a metric on  $X$ . To show that  $f, g \in X$  are equal, instead of checking that infinitely many values are equal (i.e.  $f(t) = g(t)$  for all  $t \in \mathbb{R}$ ), it suffices to check that one value (i.e.  $d(f, g)$ ) is zero.

**Remark 2.3.** Triangle inequality clearly implies “polygon inequality”:

$$d(x_0, x_n) \leq \sum_{j=1}^n d(x_{j-1}, x_j) \quad (2.2)$$

**Remark 2.4.** Choose distinct points  $x, y \in X$ . Then  $x, y$  are separated by two open balls centered at them: there exists  $r, \rho > 0$  such that  $B(x, r) \cap B(y, \rho) = \emptyset$ . This is called the **Hausdorff property**.

To see this fact, note that  $d(x, y) > 0$ . Choose  $r, \rho$  such that  $r + \rho \leq d(x, y)$ . If  $z \in B(x, r) \cap B(y, \rho)$ , then  $d(x, z) + d(y, z) < r + \rho \leq d(x, y)$ , contradicting triangle inequality.

We will see (cf. Prop. 2.19) that Hausdorff property guarantees that any sequence in a metric space cannot converge to two different points. Intuition: one cannot find a point which is very close to  $x$  and  $y$  at the same time.  $\square$

We give some examples, and leave it to the readers to check that they satisfy the definition of metric spaces. We assume that square roots of positive real numbers can be defined. (We will rigorously define square roots after we define  $e^x$  using the series  $\sum_{n \in \mathbb{N}} x^n / n!$ .)

**Example 2.5.**  $\mathbb{R}$  is a metric space if we define  $d(x, y) = |x - y|$

<sup>5</sup>We want open and closed balls to be nonempty. So we assume  $r \neq 0$  only for open balls.

**Example 2.6.** On  $\mathbb{R}^n$ , we can define **Euclidean metric**

$$d(x, y) = \sqrt{(x_1 - y_1)^2 + \cdots + (x_n - y_n)^2}$$

if  $x_\bullet, y_\bullet$  are the components of  $x, y$ . The following are also metrics:

$$\begin{aligned} d_1(x, y) &= |x_1 - y_1| + \cdots + |x_n - y_n| \\ d_\infty(x, y) &= \max\{|x_1 - y_1|, \dots, |x_n - y_n|\} \end{aligned}$$

**Example 2.7.** The **Euclidean metric** on  $\mathbb{C}^n$  is

$$d(z, w) = \sqrt{|z_1 - w_1|^2 + \cdots + |z_n - w_n|^2}$$

which agrees with the Euclidean metric on  $\mathbb{R}^{2n}$ . The following are also metrics:

$$\begin{aligned} d_1(z, w) &= |z_1 - w_1| + \cdots + |z_n - w_n| \\ d_\infty(z, w) &= \max\{|z_1 - w_1|, \dots, |z_n - w_n|\} \end{aligned}$$

**Convention 2.8.** Unless otherwise stated, the metrics on  $\mathbb{R}^n$  and  $\mathbb{C}^n$  (and their subsets) are assumed to be the Euclidean metrics.

**Remark 2.9.** One may wonder what the subscripts  $1, \infty$  mean. This notation is actually due to the general fact that

$$d_p(z, w) = \sqrt[p]{|z_1 - w_1|^p + \cdots + |z_n - w_n|^p}$$

is a metric where  $1 \leq p < +\infty$ , and  $d_\infty = \lim_{q \rightarrow +\infty} d_q$ . It is not easy to prove that  $d_p$  satisfies triangle inequality: one needs Minkowski inequality. For now, we will not use such general  $d_p$ . And we will discuss Minkowski inequality in later sections.

**Example 2.10.** Let  $X = X_1 \times \cdots \times X_N$  where each  $X_i$  is a metric space with metric  $d_i$ . Write  $x = (x_1, \dots, x_N) \in X$  and  $y = (y_1, \dots, y_N) \in Y$ . Then the following are metrics on  $X$ :

$$\begin{aligned} d(x, y) &= d_1(x_1, y_1) + \cdots + d_N(x_N, y_N) \\ \delta(x, y) &= \max\{d_1(x_1, y_1), \dots, d_N(x_N, y_N)\} \\ \rho(x, y) &= \sqrt{d_1(x_1, y_1)^2 + \cdots + d_N(x_N, y_N)^2} \end{aligned}$$

With respect to the metric  $\delta$ , the open balls of  $X$  are “polydisks”

$$B_X(x, r) = B_{X_1}(x_1, r) \times \cdots \times B_{X_N}(x_N, r)$$

There is no standard choice of metric on the product of metric spaces.  $d, \delta, \rho$  are all good, and they are equivalent in the following sense:

**Definition 2.11.** We say that two metrics  $d_1, d_2$  on a set  $X$  are **equivalent** and write  $d_1 \approx d_2$ , if there exist  $\alpha, \beta > 0$  such that for any  $x, y \in X$  we have

$$d_1(x, y) \leq \alpha d_2(x, y) \quad d_2(x, y) \leq \beta d_1(x, y)$$

This is an equivalence relation. More generally, we may write  $d_1 \lesssim d_2$  if  $d_1 \leq \alpha d_2$  for some  $\alpha > 0$ . Then  $d_1 \approx d_2$  iff  $d_1 \lesssim d_2$  and  $d_2 \lesssim d_1$ .

**Example 2.12.** In Exp. 2.10, we have  $\delta \leq \rho \leq d \leq N\delta$ . So  $\delta \approx \rho \approx d$ .

**Convention 2.13.** Given finitely many metric spaces  $X_1, \dots, X_N$ , the metric on their product space  $X = X_1 \times \dots \times X_N$  is chosen to be any one that is equivalent to the ones defined in Exp. 2.10. In the case that each  $X_i$  is a subset of  $\mathbb{R}$  or  $\mathbb{C}$ , we follow Convention 2.8 and choose the metric on  $X$  to be the Euclidean metric (unless otherwise stated).

**Definition 2.14.** Let  $(X, d)$  be a metric space. Then a **metric subspace** is denoted an object  $(Y, d|_Y)$  where  $Y \subset X$  and  $d|_Y$  is the restriction of  $d$  to  $Y$ , namely, for all  $y_1, y_2 \in Y$  we set

$$d|_Y(y_1, y_2) = d(y_1, y_2)$$

**Convention 2.15.** Suppose  $Y$  is a subset of a given metric space  $(X, d)$ . Unless otherwise stated, the metric of  $Y$  is chosen to be  $d|_Y$  whenever  $Y$  is viewed as a metric space. For example, the metric of any subset of  $\mathbb{R}^n$  is assumed to be the Euclidean metric, unless otherwise stated.

## 2.3 Convergence of sequences

**Definition 2.16.** Let  $(x_n)_{n \in \mathbb{Z}_+}$  be a sequence in a metric space  $X$ . Let  $x \in X$ . We say that  $x$  is the **limit** of  $x_n$  and write  $\lim_{n \rightarrow \infty} x_n = x$  (or  $x_n \rightarrow x$ ), if:

- For every real number  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that for every  $n \geq N$  we have  $d(x_n, x) < \varepsilon$ .

Equivalently, this means that every (nonempty) open ball centered at  $x$  contains **all but finitely many**  $x_n$ .<sup>6</sup>

**Remark 2.17.** The negation of  $x_n \rightarrow x$  is clear:

- There exists  $\varepsilon > 0$  such that for all  $N \in \mathbb{Z}_+$  there exists  $n \geq N$  such that  $d(x_n, x) \geq \varepsilon$ .

---

<sup>6</sup>“All but finitely many  $x_n$  satisfies...” means “for all but finitely many  $n$ ,  $x_n$  satisfies...”. It does NOT mean that “all but finitely many elements of the set  $\{x_n : n \in \mathbb{Z}_+\}$  satisfies...”.

Namely, one changes each “for all” to “there exists”, changes each “there exists” to “for all”, and negate the last sentence.

**Exercise 2.18.** Show that in the above definition of limits, it suffices to consider rational numbers  $\varepsilon > 0$ . (Note: You need to use Prop. 1.29.)

This exercise implies that the definition of limits does not require the existence of real numbers, i.e., does not assume Thm. 1.34. Indeed, we will use limits of sequences (and “double sequences”) to prove Thm. 1.34.

In many textbooks and research papers, you will see phrases such as

$$x_n \text{ satisfies property } P \text{ for sufficiently large } n \quad (2.3)$$

This means that “there exists  $N \in \mathbb{Z}_+$  such that  $P$  holds for all  $n \geq N$ ”. (We also say that  $x_n$  **eventually** satisfies  $P$ .) Then  $\lim_{n \rightarrow \infty} x_n = x$  means that “for every  $\varepsilon > 0$ , we have  $d(x_n, x) < \varepsilon$  for sufficiently large  $n$ ”.

**Proposition 2.19.** Any sequence  $(x_n)_{n \in \mathbb{Z}_+}$  in a metric space  $X$  has at most one limit.

*Proof.* Suppose  $(x_n)_{n \in \mathbb{Z}_+}$  converges to  $x, y \in X$  where  $x \neq y$ . By Hausdorff property (Rem. 2.4), there exist  $r, \rho > 0$  such that  $B(x, r) \cap B(y, \rho) = \emptyset$ . By the definition of  $x_n \rightarrow x$ , there exists  $N_1 \in \mathbb{Z}_+$  such that  $x_n \in B(x, r)$  for all  $n \geq N_1$ . Similarly,  $x_n \rightarrow y$  means that there is  $N_2 \in \mathbb{Z}_+$  such that  $x_n \in B(y, \rho)$  for all  $n \geq N_2$ . Choose any  $n \geq N_1, N_2$  (e.g.  $n = \max\{N_1, N_2\}$ ). Then  $x_n \in B(x, r) \cap B(y, \rho) = \emptyset$ , impossible.  $\square$

### 2.3.1 Methods for proving convergence and computing limits

**Example 2.20.**  $\lim_{n \rightarrow \infty} \frac{1}{n} = 0$ .

*Proof.* Choose any  $\varepsilon \in \mathbb{Q}_{>0}$ . By Archimedean property, there exists  $N \in \mathbb{Z}_+$  such that  $N\varepsilon > 1$ , i.e.  $1/N < \varepsilon$ . Thus, for all  $n \geq N$  we have  $1/n < \varepsilon$ .  $\square$

**Proposition 2.21.** Let  $\mathbb{F} \in \{\mathbb{Q}, \mathbb{R}\}$  and  $(x_n), (y_n)$  be sequences in  $\mathbb{F}$  converging to  $x, y \in \mathbb{R}$ . If  $x_n \leq y_n$  for all  $n$ , then  $x \leq y$ .

*Proof.* If  $y < x$ , let  $\varepsilon = x - y$ . Then all but finitely many members of  $(x_n)$  are in  $(x - \varepsilon/2, x + \varepsilon/2)$ , and all but finitely many members of  $(y_n)$  are in  $(y - \varepsilon/2, y + \varepsilon/2)$ . Since  $y + \varepsilon/2 < x - \varepsilon/2$ , there must exist  $n$  such that  $y_n < x_n$ .  $\square$

**Definition 2.22.** If  $A$  and  $B$  are posets (or more generally, preordered sets, see Def. 5.1), we say a function  $f : A \rightarrow B$  is **increasing** (resp. **strictly increasing**), if for each  $x, y \in A$  we have

$$x \leq y \quad \implies \quad f(x) \leq f(y)$$

$$\begin{array}{ccc} & \text{resp.} & \\ x < y & \implies & f(x) < f(y) \end{array}$$

We leave the definitions of **decreasing** and **strictly decreasing** to the readers. We say that  $f$  is **monotonic** (resp. **strictly monotonic**), if  $f$  is either increasing or decreasing (resp. either strictly increasing or strictly decreasing).

**Proposition 2.23.** *Let  $(x_n)_{n \in \mathbb{Z}}$  be a sequence in  $[a, b] \subset \mathbb{R}$ . If  $(x_n)$  is increasing (resp. decreasing), then  $\lim_{n \rightarrow \infty} x_n$  equals  $\sup\{x_n : n \in \mathbb{Z}_+\}$  (resp.  $\inf\{x_n : n \in \mathbb{Z}_+\}$ ).*

*Proof.* Assume  $(x_n)$  increases. (The case of decreasing is similar and hence its proof is omitted.) Let  $A = \sup\{x_n : n \in \mathbb{Z}_+\} < +\infty$ . Then for each  $\varepsilon > 0$  there is  $N$  such that  $x_N > A - \varepsilon$  (since  $A - \varepsilon$  is not an upper bound). Since  $(x_n)$  is increasing, for all  $n \in \mathbb{N}$  we have  $A - \varepsilon < x_n \leq A$  and so  $|x_n - A| < \varepsilon$ .  $\square$

**Example 2.24.** Let  $(x_n)_{n \in \mathbb{Z}_+}$  be a sequence in a metric space  $X$ , and let  $x \in X$ . It is easy to see that

$$\lim_{n \rightarrow \infty} x_n = x \iff \lim_{n \rightarrow \infty} d(x_n, x) = 0$$

**Example 2.25.** Suppose that  $(a_n)$  and  $(b_n)$  are sequences in  $\mathbb{R}_{\geq 0}$ , that  $a_n \leq b_n$  for all  $n$ , and that  $b_n \rightarrow 0$ . Then  $a_n \rightarrow 0$ .

*Proof.* For each  $\varepsilon > 0$ ,  $[0, \varepsilon)$  contains all but finitely many  $b_n$ , and hence all but finitely many  $a_n$ .  $\square$

More generally, we have:

**Proposition 2.26 (Squeeze theorem).** *Suppose that  $(x_n)$  is a sequence in a metric space  $X$ . Let  $x \in X$ . Suppose that there is a sequence  $(a_n)$  in  $\mathbb{R}_{\geq 0}$  such that  $\lim_{n \rightarrow \infty} a_n = 0$  and that  $d(x_n, x) \leq a_n$  for all  $n$ . Then  $\lim_{n \rightarrow \infty} x_n = x$ .*

*Proof.* This follows immediately from Exp. 2.24 and 2.25.  $\square$

The above proposition explains why many people say that “analysis is the art of inequalities”: It transforms the problem of convergence to the problem of finding a sequence  $(a_n) \in \mathbb{R}_{\geq 0}$  converging to 0 such that the inequality  $d(x_n, x) \leq a_n$  holds. And very often, a good (hard) analyst is one who knows how to find such good sequences!

**Proposition 2.27.** *Let  $X = X_1 \times \cdots \times X_N$  be a product of metric spaces  $(X_i, d_i)$ . Let  $d$  be any of the three metrics of  $X$  in Exp. 2.10. Let  $\mathbf{x}_n = (x_{1,n}, \dots, x_{N,n})$  be a sequence in  $X$ . Let  $\mathbf{y} = (y_1, \dots, y_N)$ . Then*

$$\lim_{n \rightarrow \infty} \mathbf{x}_n = \mathbf{y} \iff \lim_{n \rightarrow \infty} x_{i,n} = y_i \quad (\forall 1 \leq i \leq N)$$

*Proof.* We let  $d$  be the metric  $\delta$  in Exp. 2.10, i.e. defined by  $\max_j d_j(x_j, y_j)$ . Now choose a sequence  $(x_n)$  and an element  $y$  in  $X$ . Then

$$x_n \rightarrow y \iff d_X(x_n, y) \rightarrow 0 \iff \max_{1 \leq j \leq N} d_j(x_{j,n}, y_j) \rightarrow 0 \quad (2.4)$$

Suppose that the RHS of (2.4) is true. Fix any  $1 \leq i \leq N$ . Then  $d_i(x_{i,n}, y_i) \leq \max_j d_j(x_{j,n}, y_j)$ . So  $x_{i,n} \rightarrow y_i$  by Prop. 2.26.

Conversely, assume that for every  $i$  we have  $x_{i,n} \rightarrow y_i$ . Then for every  $\varepsilon > 0$  there is  $K_i \in \mathbb{Z}_+$  such that  $d_i(x_{i,n}, y_i) < \varepsilon$  for every  $n \geq K_i$ . Let  $K = \max\{K_1, \dots, K_N\}$ . Then for all  $n \geq K$  we have  $\max_j d_j(x_{j,n}, y_j) < \varepsilon$ . This proves the RHS of (2.4).

If  $d$  is one of the other two metrics in Exp. 2.10, one can either use a similar argument, or use the following important (but easy) fact.  $\square$

**Proposition 2.28.** *Let  $d, \delta$  be two equivalent metrics on a set  $X$ . Let  $(x_n)_{n \in \mathbb{Z}_+}$  and  $x$  be in  $X$ . Then  $(x_n)$  converges to  $x$  under the metric  $d$  iff  $(x_n)$  converges to  $x$  under  $\delta$ . Namely,  $d(x_n, x) \rightarrow 0$  iff  $\delta(x_n, x) \rightarrow 0$ .*

*Proof.* Prove it yourself. (Or see Prop. 2.62.)  $\square$

More useful formulas about limit will be given in Exp. 4.24.

### 2.3.2 Criteria for divergence

**Definition 2.29.** A subset  $E$  of a metric space  $(X, d)$  is called **bounded** if either  $E = \emptyset$  or there exist  $p \in X$  and  $R \in \mathbb{R}_{>0}$  such that  $E \subset B_X(p, R)$ . If  $X$  is bounded, we also say that  $d$  is a **bounded metric**.

**Remark 2.30.** Note that if  $E$  is bounded, then for any  $q \in X$  there exists  $\tilde{R} \in \mathbb{R}_{>0}$  such that  $E \subset B_X(q, \tilde{R})$ . (Indeed, choose  $\tilde{R} = R + d(p, q)$ , then by triangle inequality,  $B(p, R) \subset B(q, \tilde{R})$ .)

Some easy examples are as follows.

**Example 2.31.** In a metric space  $X$ , if  $x \in X$  and  $0 < r < +\infty$ , then  $B(x, r)$  is bounded. Hence  $\overline{B}(x, r)$  is bounded (since it is inside  $B(x, 2r)$ ).

Also, it is easy to see:

**Example 2.32.** A finite union of bounded subsets is bounded.

**Proposition 2.33.** *Let  $(x_n)_{n \in \mathbb{Z}_+}$  be a convergent sequence in a metric space  $X$ . Then  $(x_n)_{n \in \mathbb{Z}_+}$  is bounded.*

By saying that a sequence  $(x_n)_{n \in \mathbb{Z}_+}$  in  $X$  is **bounded**, we mean that its range in  $X$  (namely  $\{x_n : n \in \mathbb{Z}_+\}$ ) is bounded.

*Proof.* Suppose that  $x_n \rightarrow x$ . Then for each  $\varepsilon > 0$ , say  $\varepsilon = 1$ , all but finitely many elements of  $x_n$  (say  $x_1, \dots, x_N$ ) are in  $B(x, 1)$ . So this whole sequence is in  $A = \{x_1\} \cup \dots \cup \{x_N\} \cup B(x, 1)$ . Since each  $\{x_i\}$  is bounded, and since  $B(x, 1)$  is bounded,  $A$  is bounded by Exp. 2.32.  $\square$

**Remark 2.34.** Prop. 2.33 gives our first criterion on divergence: If a sequence is unbounded (e.g.  $x_n = n^2$ ), then it does not converge. But there are many bounded and divergent sequences. (See Exp. 2.37.) In this case, we need the second criterion: If a sequence has two subsequences converging to two different points, then this sequence diverge. (See Prop. 2.36)

**Definition 2.35.** Let  $(x_n)_{n \in \mathbb{Z}_+}$  be a sequence in a set  $X$ . If  $(n_k)_{k \in \mathbb{Z}_+}$  is a strictly increasing sequence in  $\mathbb{Z}_+$ , we say that  $(x_{n_k})_{k \in \mathbb{Z}_+}$  is a **subsequence** of  $(x_n)_{n \in \mathbb{Z}_+}$ .

Thus, a subsequence of  $(x_n)_{n \in \mathbb{Z}_+}$  is equivalently the restriction of the function  $x : \mathbb{Z}_+ \rightarrow X$  to an infinite subset of  $\mathbb{Z}_+$ .

**Proposition 2.36.** Let  $(x_n)_{n \in \mathbb{Z}_+}$  be a sequence in a metric space  $X$  converging to  $x \in X$ . Then every subsequence  $(x_{n_k})_{k \in \mathbb{Z}_+}$  converges to  $x$ .

*Proof.* For every  $\varepsilon > 0$ ,  $B(x, \varepsilon)$  contains all but finitely many  $\{x_n : n \in \mathbb{Z}_+\}$ , and hence all but finitely many  $\{x_{n_k} : k \in \mathbb{Z}_+\}$ .  $\square$

**Example 2.37.** The sequence  $x_n = (-1)^n$  in  $\mathbb{R}$  is divergent, because the subsequence  $(x_{2k})_{k \in \mathbb{Z}_+}$  converges to 1, whereas  $(x_{2k-1})_{k \in \mathbb{Z}_+}$  converges to  $-1$ .

One may wonder if the two criteria in Rem. 2.34 are complete in order to determine whether a sequence diverges. This is true for sequences in  $\mathbb{R}^n$ . We will discuss this topic later. (See Cor. 3.17.)

## 2.4 Continuous maps of metric spaces

Continuous maps are a powerful tool for showing that a sequence converges.

**Definition 2.38.** Let  $f : X \rightarrow Y$  be a map of metric spaces. Let  $x \in X$ . We say that  $f$  is **continuous at  $x$**  if one of the following equivalent conditions hold:

(1) For every sequence  $(x_n)_{n \in \mathbb{Z}_+}$  in  $X$ , we have

$$\lim_{n \rightarrow \infty} x_n = x \quad \implies \quad \lim_{n \rightarrow \infty} f(x_n) = f(x)$$

(2) For every  $\varepsilon > 0$ , there exists  $\delta > 0$  such that for every  $p \in X$  satisfying  $d(p, x) < \delta$ , we have  $d(f(p), f(x)) < \varepsilon$ .

(2') For every  $\varepsilon > 0$ , there exists  $\delta > 0$  such that  $B_X(x, \delta) \subset f^{-1}(B_Y(f(x), \varepsilon))$ .

We say that  $f$  is a **continuous map/function**, if  $f$  is continuous at every point of  $X$ .

*Proof of the equivalence.* (2) $\Leftrightarrow$ (2'): Obvious.

(2) $\Rightarrow$ (1): Assume (2). Assume  $x_n \rightarrow x$ . For every  $\varepsilon > 0$ , let  $\delta > 0$  be as in (2). Then since  $x_n \rightarrow x$ , there is  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  we have  $d(x_n, x) < \delta$ . By (2), we have  $d(f(x_n), f(x)) < \varepsilon$  for all  $n \geq N$ . This proves  $f(x_n) \rightarrow f(x)$ .

$\neg(2) \Rightarrow \neg(1)$ : Assume that (2) is not true. Then there exists  $\varepsilon > 0$  such that for every  $\delta > 0$ , there exists  $p \in X$  such that  $d(p, x) < \delta$  and  $d(f(p), f(x)) \geq \varepsilon$ . Thus, for every  $n \in \mathbb{Z}_+$ , by taking  $\delta = 1/n$ , we see that there exists  $x_n \in X$  such that  $d(x_n, x) < 1/n$  and  $d(f(x_n), f(x)) \geq \varepsilon$ . By Squeeze theorem (Prop. 2.26),  $x_n \rightarrow x$ . But  $f(x_n) \not\rightarrow f(x)$  (i.e.  $d(f(x_n), f(x)) \not\rightarrow 0$ ). So (1) is not true.  $\square$

**Remark 2.39.** One can compare Def. 2.38-(1) to the definition of linear maps. A map is continuous iff it *preserves the convergence of sequences*, i.e., iff it maps convergent sequences to convergent ones. A map (between vector spaces) is linear iff it preserves the addition and the scalar multiplication of vectors. In general, a good map between two sets with “structures” is a map which preserves the structures. (Thus, linear combinations encode the linear structures of vector spaces. Similarly, the convergence of sequences remembers the “topological” structures of metric spaces.) As another example, we will define an isometry of metric spaces to be one that preserves the metrics (the structures of metric spaces), see Exe. 2.63.

**Remark 2.40.** In this section, we mainly use Def. 2.38-(1) to study continuity. But in later sections we will also use Def. 2.38-(2'). An advantage of (2') is that it is more geometric. Indeed, if  $X$  is a metric space and  $E \subset X$ , we say that  $x \in E$  is an **interior point of  $E$  in  $X$**  if there exists  $\delta > 0$  such that  $B_X(x, \delta) \subset E$ . For example, a point  $z \in \mathbb{C}$  is an interior point of the closed unit disk  $\overline{B}_{\mathbb{C}}(0, 1) = \{w \in \mathbb{C} : |w| \leq 1\}$  iff  $|z| < 1$ .

Thus, Def. 2.38-(2') says that for any map of metric spaces  $f : X \rightarrow Y$  and  $x \in X$ , the following are equivalent:

- (a)  $f$  is continuous at  $x$ .
- (b) For each  $\varepsilon > 0$ , every  $x \in X$  is an interior point of  $f^{-1}(B_Y(f(x), \varepsilon))$ .

We say that a subset  $U \subset X$  is **open** if each point of  $U$  is an interior point. For example, by triangle inequality, every open ball in a metric space is an open set. Thus, we have:

- A map of metric spaces  $f : X \rightarrow Y$  is continuous iff the preimage under  $f$  of every open ball of  $Y$  is an open subset of  $X$ .

In the study of point-set topology, we will see that many properties can be studied in two approaches: using sequences (or using nets, the natural generalizations of sequences) and their convergence, and using open sets. The first example

of such property is continuity, as we have seen in Def. 2.38. Another prominent example is sequential compactness vs. compactness. These two approaches represent two (very) different intuitions: one is dynamic, while the other is static and more geometric. (So it is surprising that these two very things are actually equivalent!) Sometimes both approaches work for a problem, but sometimes only one of them works, or one of them is much simpler. If you are a beginner in analysis and point-set topology, I suggest that whenever you see one approach applied to a problem, try to think about whether the other approach also works and which one is better.  $\square$

## 2.4.1 Methods for proving continuity

**Lemma 2.41.** *Let  $f : X \rightarrow Y$  be a map of metric spaces. Let  $(B_i)_{i \in I}$  be a collection of open balls in  $X$  such that  $X = \bigcup_{i \in I} B_i$ . Suppose that for each  $i$ , the restriction  $f|_{B_i} : B_i \rightarrow Y$  is continuous. Then  $f$  is continuous.*

This lemma shows that if we can prove that  $f$  is “locally” continuous, then  $f$  is globally continuous.

*Proof.* Choose  $(x_n)$  in  $X$  converging to  $x \in X$ . We shall show  $f(x_n) \rightarrow f(x)$ . Choose  $i$  such that  $x \in B_i$ . Then one can find  $\delta > 0$  such that  $B(x, \delta) \subset B_i$ . (In the language of point-set topology:  $x$  is an interior point of  $B_i$ .) To see this, write  $B_i = B(y, r)$ . Since  $x \in B(y, r)$ , we have  $r - d(x, y) > 0$ . Choose  $0 < \delta \leq r - d(x, y)$ . Then triangle inequality implies  $B(x, \delta) \subset B(y, r)$ .

Since  $x_n \rightarrow x$ , there is  $N \in \mathbb{Z}_+$  such that  $x_n \in B(x, \delta)$  for all  $n \geq N$ . Thus,  $(x_{k+N})_{k \in \mathbb{Z}_+}$  converges in  $B_i$  to  $x$ . Since  $f|_{B_i}$  is continuous,  $\lim_{k \rightarrow \infty} f(x_{k+N}) = f(x)$ . So  $f(x_n) \rightarrow f(x)$ .  $\square$

**Definition 2.42.** A map of metric spaces  $f : X \rightarrow Y$  is called **Lipschitz continuous** if there exists  $L \in \mathbb{R}_{>0}$  (called **Lipschitz constant**) such that for all  $x_1, x_2 \in X$ ,

$$d_Y(f(x_1), f(x_2)) \leq L \cdot d_X(x_1, x_2) \quad (2.5)$$

**Lemma 2.43.** *Lipschitz continuous maps are continuous.*

*Proof.* Suppose that  $f : X \rightarrow Y$  is Lipschitz continuous with Lipschitz constant  $L$ . Suppose  $x_n \rightarrow x$  in  $X$ . Then  $L \cdot d(x_n, x) \rightarrow 0$ . By (2.5) and Squeeze theorem (Prop. 2.26),  $f(x_n) \rightarrow f(x)$ . (You can also use Def. 2.38-(2) to prove this lemma.)  $\square$

**Example 2.44.** Let  $\mathbb{F} \in \{\mathbb{Q}, \mathbb{R}, \mathbb{C}\}$ . The map  $z \in \mathbb{F} \setminus \{0\} \mapsto z^{-1} \in \mathbb{F}$  is continuous.

*Proof.* Let this map be  $f$ . Since  $\mathbb{F}$  is covered by open balls  $B(z, \delta)$  where  $z \in \mathbb{F} \setminus \{0\}$  and  $0 < \delta < |z|$ , by Lem. 2.41, it suffices to prove that  $f$  is continuous when restricted to every such  $B(z, \delta)$ . Let  $\varepsilon = |z| - \delta > 0$ . Choose  $x, y \in B(z, \delta)$ . Then  $|x| = |x - z + z| \geq |z| - |z - x| > \varepsilon$  by triangle inequality. Similarly,  $|y| > \varepsilon$ . So

$$|f(x) - f(y)| = |x^{-1} - y^{-1}| = |x - y|/|xy| \leq \varepsilon^{-2}|x - y|$$

So  $f|_{B(z, \delta)}$  has Lipschitz constant  $\varepsilon^{-2}$ , and hence is continuous.  $\square$

(Question: in the above proof, is the map  $f : \mathbb{F} \setminus \{0\} \rightarrow \mathbb{F}$  Lipschitz continuous?)

We have given a fancy way of proving that if  $(z_n)$  is a sequence in  $\mathbb{F} \setminus \{0\}$  converging to  $z \in \mathbb{F} \setminus \{0\}$ , then  $z_n^{-1} \rightarrow z^{-1}$ . You should think about how to prove this fact directly using  $\varepsilon - N$  language, and compare your proof with the above proof to find the similarities!

**Proposition 2.45.** *Let  $\mathbb{F} \in \{\mathbb{Q}, \mathbb{R}, \mathbb{C}\}$ . Then the following maps are continuous:*

$$\begin{aligned} + : \mathbb{F} \times \mathbb{F} &\rightarrow \mathbb{F} & (x, y) &\mapsto x + y \\ - : \mathbb{F} \times \mathbb{F} &\rightarrow \mathbb{F} & (x, y) &\mapsto x - y \\ \times : \mathbb{F} \times \mathbb{F} &\rightarrow \mathbb{F} & (x, y) &\mapsto xy \\ \div : \mathbb{F} \times \mathbb{F}^\times &\rightarrow \mathbb{F} & (x, y) &\mapsto x/y \end{aligned}$$

Recall our Convention 2.13 on the metrics of finite product spaces.

*Proof.* We only prove that the last two are continuous: the first two can be treated in a similar (and easier) way.

Denote the multiplication map by  $\mu$ . We choose the metric on  $\mathbb{F}^2$  to be  $d(\mathbf{x}, \mathbf{x}') = \max\{|x_1 - x'_1|, |x_2 - x'_2|\}$ . Since  $\mathbb{F} \times \mathbb{F}$  is covered by open balls of the form  $B(0, r) = \{(x, y) \in \mathbb{F}^2 : |x| < r, |y| < r\}$  where  $0 < r < +\infty$ , by Lem. 2.41 and 2.43, it suffices to show that  $\mu|_{B(0, r)}$  is Lipschitz continuous. This is true, since for each  $(x, y), (x', y') \in B(0, r)$ , we have

$$\begin{aligned} |\mu(x, y) - \mu(x', y')| &= |xy - x'y'| \leq |(x - x')y| + |x'(y - y')| \\ &< 2r \cdot \max\{|x - x'|, |y - y'|\} = 2r \cdot d((x, y), (x', y')) \end{aligned} \quad (2.6)$$

By Exp. 2.44 and Prop. 2.47, the map  $(x, y) \in \mathbb{F} \times \mathbb{F}^\times \mapsto (x, y^{-1}) \in \mathbb{F} \times \mathbb{F}$  is continuous. So its composition with the continuous map  $\mu$  is continuous, thanks to Prop. 2.46. So  $\div$  is continuous.  $\square$

**Proposition 2.46.** *Suppose that  $f : X \rightarrow Y$  and  $g : Y \rightarrow Z$  are continuous maps of metric spaces. Then  $g \circ f : X \rightarrow Z$  is continuous.*

**Proposition 2.47.** *Suppose that  $f_i : X_i \rightarrow Y_i$  is a map of metric spaces, where  $1 \leq i \leq N$ . Then the product map*

$$\begin{aligned} f_1 \times \cdots \times f_N : X_1 \times \cdots \times X_N &\rightarrow Y_1 \times \cdots \times Y_N \\ (x_1, \dots, x_N) &\mapsto (f_1(x_1), \dots, f_N(x_N)) \end{aligned}$$

*is continuous if and only if  $f_1, \dots, f_N$  are continuous.*

*Proof of Prop. 2.46 and 2.47.* Immediate from Def. 2.38-(1) and Prop. 2.27.  $\square$

**Corollary 2.48 (Squeeze theorem).** *Let  $\mathbb{F} \in \{\mathbb{Q}, \mathbb{R}\}$  and  $(x_n), (y_n), (z_n)$  be sequences in  $\mathbb{R}$ . Assume that  $x_n \leq y_n \leq z_n$  for all  $n$ . Assume that  $x_n$  and  $z_n$  both converge to  $A \in \mathbb{R}$ . Then  $\lim_{n \rightarrow \infty} y_n = A$ .*

*Proof.* Let  $a_n = y_n - x_n$  and  $b_n = z_n - x_n$ . Then  $0 \leq a_n \leq b_n$ , and  $\lim_n b_n = \lim_n z_n - \lim_n x_n = 0$  because the subtraction map is continuous (Prop. 2.45). By Exp. 2.25,  $a_n \rightarrow 0$ . Since  $x_n \rightarrow A$ ,  $y_n = x_n + a_n$  converges to  $A$ , since the addition map is continuous by Prop. 2.45.  $\square$

Again, this is a fancy way of proving Squeeze theorem. The readers should know how to prove it directly from the definition of limits of sequences.

We give some more examples of continuous maps.

**Example 2.49.** By Prop. 2.45,  $f(x, y, z) = x^2y + 5y^4z^7 - 3xyz^2$  is a continuous function on  $\mathbb{C}^3$ . Clearly  $z \in \mathbb{C} \mapsto \bar{z} \in \mathbb{C}$  is continuous. So  $g(x, y, z) = f(\bar{x}, \bar{y}, z) + 2f(z, x^2, xy^{-9}) - 5xy^{-2}\bar{z}^{-3}$  is a continuous function on  $\mathbb{C} \times \mathbb{C}^\times \times \mathbb{C}^\times$ .

**Example 2.50.** Let  $f, g : X \rightarrow \mathbb{F}$  be continuous functions where  $\mathbb{F} \in \{\mathbb{Q}, \mathbb{R}, \mathbb{C}\}$ . Then by Prop. 2.45 and 2.46,  $f \pm g$  and  $fg$  are continuous, and  $f/g$  is continuous when  $0 \notin g(X)$ . Here

$$(f \pm g)(x) = f(x) \pm g(x) \quad (fg)(x) = f(x)g(x) \quad (f/g)(x) = f(x)/g(x) \quad (2.7)$$

**Example 2.51.** Let  $f : X \rightarrow Y$  be a map of metric spaces. Let  $E, F$  be subsets of  $X, Y$  respectively. (Recall that the metrics of subsets are chosen as in Def. 2.14.)

- The inclusion map  $\iota_E : E \rightarrow X, x \mapsto x$  is clearly continuous. Thus, if  $f$  is continuous, then  $f|_E : E \rightarrow Y$  is continuous, since  $f|_E = f \circ \iota_E$ .
- If  $f(X) \subset F$ , then we can restrict the codomain of  $f$  from  $Y$  to  $F$ : let  $\tilde{f} : X \rightarrow F$  be  $\tilde{f}(x) = f(x)$ . Then it is clear that  $f$  is continuous iff  $\tilde{f}$  is continuous.

**Proposition 2.52.** Let  $X_1, \dots, X_N$  be metric spaces. The following projection is clearly continuous:

$$\pi_{X_i} : X_1 \times \dots \times X_N \rightarrow X_i \quad (x_1, \dots, x_N) \mapsto x_i$$

**Proposition 2.53.** Let  $f_i : X \rightarrow Y_i$  be maps where  $X, Y_1, \dots, Y_N$  are continuous. Then

$$f_1 \vee \dots \vee f_N : X \rightarrow Y_1 \times \dots \times Y_N \quad x \mapsto (f_1(x), \dots, f_N(x))$$

is continuous iff  $f_1, \dots, f_N$  are continuous.

**Example 2.54.** Let  $X$  be a metric space. Then  $d : X \times X \rightarrow \mathbb{R}, (x, y) \mapsto d(x, y)$  is Lipschitz continuous with Lipschitz constant 1 (by triangle inequality). So  $d$  is continuous.

**Proposition 2.55.** Let  $X$  be a metric space and  $E \subset X$ . Define **distance function**

$$d(\cdot, E) : X \rightarrow \mathbb{R}_{\geq 0} \quad d(x, E) = \inf_{e \in E} d(x, e)$$

Then  $d(\cdot, E)$  has Lipschitz constant 1. So  $d(\cdot, E)$  is continuous.

*Proof.* Choose any  $x, y \in X$ . By triangle inequality, for each  $e \in E$  we have  $d(x, e) \leq d(x, y) + d(y, e)$ . Since  $d(x, E) \leq d(x, e)$ , we get  $d(x, E) \leq d(x, y) + d(y, e)$ . Applying  $\inf_{e \in E}$  to the RHS gives  $d(x, E) \leq d(x, y) + d(y, E)$ . Hence  $d(x, E) - d(y, E) \leq d(x, y)$ . Exchanging  $x$  and  $y$  gives

$$|d(x, E) - d(y, E)| \leq d(x, y) \quad (2.8)$$

This proves that  $d(\cdot, E)$  has Lipschitz constant 1.  $\square$

**Definition 2.56.** More generally, if  $E, F$  are subsets of a metric space  $E$ , we can define

$$d(E, F) = \inf_{e \in E, f \in F} d(e, f) \quad (2.9)$$

to be the **distance between  $E$  and  $F$** .

**Exercise 2.57.** Let  $E, F \subset X$ . Prove that

$$d(E, F) = \inf_{f \in F} d(E, f) \quad (2.10)$$

**Example 2.58.** If  $X$  is a metric space and  $p \in X$ , then by Prop. 2.55 (or simply by triangle inequality), the function  $d_p : x \in X \mapsto d(x, p) \in \mathbb{R}$  has Lipschitz constant 1 and hence is continuous. In particular, if  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ , the function  $z \in \mathbb{F} \mapsto |z|$  is continuous (since  $|z| = d_{\mathbb{F}}(z, 0)$ ). Thus, if  $f : X \rightarrow \mathbb{F}$  is continuous, then  $|f| : X \rightarrow \mathbb{R}_{\geq 0}$  is continuous where

$$|f|(x) = |f(x)| \quad (2.11)$$

**Example 2.59.** Let  $N \in \mathbb{Z}_+$ . Then the following function is continuous:

$$\max : \mathbb{R}^N \rightarrow \mathbb{R} \quad (x_1, \dots, x_N) \mapsto \max\{x_1, \dots, x_N\} \in \mathbb{R}$$

Similarly, the minimum function is continuous.

*Proof.* To avoid confusion, we write  $\max$  as  $\max_N$ . The case  $N = 1$  is obvious. When  $N = 2$ , we have

$$\max(x_1, x_2) = \frac{x_1 + x_2 + |x_1 - x_2|}{2} \quad (2.12)$$

So  $\max_2$  is continuous by Exp. 2.50 and 2.58.

We use induction. Suppose we have proved that  $\max_N$  is continuous. Then  $\max_N \times \text{id}_{\mathbb{R}} : \mathbb{R}^N \times \mathbb{R} \rightarrow \mathbb{R} \times \mathbb{R}$  is continuous. So  $\max_{N+1} = \max_2 \circ (\max_N \times \text{id}_{\mathbb{R}})$  is continuous.  $\square$

## 2.5 Homeomorphisms and isometric isomorphisms; convergence in $\overline{\mathbb{R}}$

### 2.5.1 General theory

**Definition 2.60.** A bijection of metric spaces  $f : X \rightarrow Y$  is called a **homeomorphism** if one of the following equivalent (cf. Def. 2.38) statements holds:

- (1)  $f : X \rightarrow Y$  and its inverse map  $f^{-1} : Y \rightarrow X$  are continuous.
- (2) For each sequence  $(x_n)$  in  $X$  and each  $x \in X$ , we have  $\lim_{n \rightarrow \infty} x_n = x$  iff  $\lim_{n \rightarrow \infty} f(x_n) = f(x)$ .

If such  $f$  exists, we say that  $X, Y$  are **homeomorphic**.

A special case of the above definition is:

**Definition 2.61.** Let  $X$  be a set with metrics  $d, \delta$ . We say that  $d$  and  $\delta$  induce the **same topology** on  $X$  (or that  $d, \delta$  are **topologically equivalent**) if one of the following clearly equivalent statements holds:

- (1) The map  $(X, d) \rightarrow (X, \delta), x \mapsto x$  is a homeomorphism.<sup>7</sup>
- (2) For each sequence  $(x_n)$  in  $X$  and each  $x \in X$ ,  $(x_n)$  converges to  $x$  under the metric  $d$  iff  $(x_n)$  converges to  $x$  under  $\delta$ .

**Proposition 2.62.** Suppose that  $d, \delta$  are equivalent metrics on a set  $X$ . Then  $d, \delta$  are topologically equivalent.

*Proof.* Suppose  $\delta \leq \alpha d$  and  $d \leq \beta \delta$  for some  $\alpha, \beta > 0$ . Then the map  $f : (X, d) \rightarrow (X, \delta), x \mapsto x$  and its inverse  $f^{-1}$  have Lipschitz constants  $\alpha$  and  $\beta$  respectively. So  $f, f^{-1}$  are continuous.  $\square$

**Exercise 2.63.** Let  $f : X \rightarrow Y$  be a map of metric spaces. We say that  $f : X \rightarrow Y$  is an **isometry** (or is **isometric**) if for all  $x_1, x_2 \in X$  we have

$$d_Y(f(x_1), f(x_2)) = d_X(x_1, x_2) \quad (2.13)$$

Show that an isometry is injective and continuous.

We say that  $f$  is an **isometric isomorphism** if  $f$  is a surjective isometry. If an isometric isomorphism between two metric spaces  $X, Y$  exists, we say that  $X$  and  $Y$  are **isometric metric spaces**. Show that an isometric isomorphism is a homeomorphism.  $\square$

---

<sup>7</sup>We prefer not to call this map the identity map, because the metrics on the source and on the target are different.

**Remark 2.64.** Isometric isomorphisms are important examples of homeomorphisms. That  $f : X \rightarrow Y$  is an isometric isomorphism means that  $X$  and  $Y$  are equivalent as metric spaces, and that this equivalence can be implemented by the bijection  $f$ .

We now look at isometric isomorphisms in a different direction. Suppose that  $f : X \rightarrow Y$  is a bijection of sets. Suppose that  $Y$  is a metric space. Then there is a unique metric  $d_X$  on  $X$  such that  $f$  is an isometric isomorphism: one defines  $d_X$  using (2.13). We write such  $d_X$  as  $f^*d_Y$ , i.e.,

$$f^*d_Y(x_1, x_2) = d_Y(f(x_1), f(x_2))$$

and call  $f^*d_Y$  the **pullback metric** of  $d_Y$  by  $f$ . □

Pullback metrics are a very useful way of constructing metrics on a set. We consider some examples below.

**Exercise 2.65.** Two metrics inducing the same topology are not necessarily equivalent metrics. For example, let  $f : [0, 1] \rightarrow [0, 1]$  be  $f(x) = x^2$ . Let  $X = [0, 1]$ , and let  $d_X$  be the Euclidean metric:  $d_X(x, y) = |x - y|$ . So

$$f^*d_X(x, y) = |x^2 - y^2|$$

is a metric on  $X$ . It is not hard to check that  $f : (X, d_X) \rightarrow (X, d_X)$  is a homeomorphism. So  $d_X$  and  $f^*d_X$  give the same topology on  $[0, 1]$  (cf. Exe. 2.66). Show that  $f^*d_X$  and  $d_X$  are not equivalent metrics.

**Exercise 2.66.** Let  $f : X \rightarrow Y$  be a bijection of sets with metrics  $d_X, d_Y$ . Show that  $d_X$  and  $f^*d_Y$  give the same topology on  $X$  iff  $f : (X, d_X) \rightarrow (Y, d_Y)$  is a homeomorphism.

In particular, if  $f : X \rightarrow X$  is a bijection, and  $d_X$  is a metric on  $X$ . Then  $d_X$  and  $f^*d_X$  give the same topology on  $X$  iff  $f : (X, d_X) \rightarrow (X, d_X)$  is a homeomorphism.

## 2.5.2 Convergence in $\overline{\mathbb{R}}$

Our second application of pullback metrics is the convergence in  $\overline{\mathbb{R}}$ .

**Definition 2.67.** We say that a sequence  $(x_n)$  in  $\overline{\mathbb{R}}$  **converges to**  $+\infty$  (resp.  $-\infty$ ), if for every  $A \in \mathbb{R}$  there is  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  we have  $x_n > A$  (resp.  $x_n < A$ ).

Suppose  $x \in \mathbb{R}$ . We say that a sequence  $(x_n)$  in  $\overline{\mathbb{R}}$  **converges to**  $x$ , if there is  $N \in \mathbb{Z}_+$  such that  $x_n \in \mathbb{R}$  for all  $n \geq N$ , and that the subsequence  $(x_{k+N})_{k \in \mathbb{Z}_+}$  converges in  $\mathbb{R}$  to  $x$ . □

This notion of convergence is weird: it is not defined by a metric. So one wonders if there is a metric  $d$  on  $\overline{\mathbb{R}}$  such that convergence of sequences under  $d$  agrees with that in Def. 2.67. We shall now find such a metric.

**Lemma 2.68.** Let  $-\infty \leq a < b \leq +\infty$  and  $-\infty \leq c < d \leq +\infty$ . Then there is a strictly increasing bijective map  $[a, b] \rightarrow [c, d]$ .

Note that this map clearly sends  $a$  to  $c$  and  $b$  to  $d$ . So it restricts to strictly increasing bijections  $(a, b) \rightarrow (c, d)$ ,  $(a, b] \rightarrow (c, d]$ ,  $[a, b) \rightarrow [c, d)$ .

*Proof.* We have a strictly increasing bijection  $f : \mathbb{R} \rightarrow (-1, 1)$  defined by (1.10).  $f$  can be extended to a strictly increasing bijective map  $\overline{\mathbb{R}} \rightarrow [-1, 1]$  if we set  $f(\pm\infty) = \pm 1$ . Thus,  $f$  restricts to a strictly increasing bijection  $[a, b] \rightarrow [f(a), f(b)]$ . Choose a linear function  $g(x) = \alpha x + \beta$  (where  $\alpha > 0$ ) giving an increasing bijection  $[f(a), f(b)] \rightarrow [0, 1]$ . Then  $h = g \circ f : [a, b] \rightarrow [0, 1]$  is a strictly increasing bijection. Similarly, we have a strictly increasing bijection  $k : [c, d] \rightarrow [0, 1]$ . Then  $k^{-1} \circ h : [a, b] \rightarrow [c, d]$  is a strictly increasing bijection.  $\square$

**Theorem 2.69.** Let  $\varphi : \overline{\mathbb{R}} \rightarrow [a, b]$  be a strictly increasing bijective map where  $[a, b] \subset \mathbb{R}$  is equipped with the Euclidean metric  $d_{[a,b]}$ . Then a sequence  $(x_n)$  in  $\overline{\mathbb{R}}$  converges to  $x \in \overline{\mathbb{R}}$  in the sense of Def. 2.67 iff  $\varphi(x_n)$  converges to  $\varphi(x)$  under the metric  $d_{[a,b]}$ . In other words, the convergence in  $\overline{\mathbb{R}}$  is given by the metric  $\varphi^* d_{[a,b]}$ .

*Proof.* Let  $y = \varphi(x)$  and  $y_n = \varphi(x_n)$ . We need to prove that  $x_n \rightarrow x$  (in the sense of Def. 2.67) iff  $y_n \rightarrow y$  (under the Euclidean metric). Write  $\psi = \varphi^{-1}$ , which is a strictly increasing map  $[a, b] \rightarrow \overline{\mathbb{R}}$ . Note that  $\varphi(+\infty) = b$  and  $\varphi(-\infty) = a$ .

Case 1:  $x \in \mathbb{R}$ . By discarding the first several terms, we may assume that  $(x_n)$  is always in  $\mathbb{R}$ . If  $x_n \rightarrow x$ , then for every  $\varepsilon > 0$ , all but finitely many  $x_n$  are inside the open interval  $(\psi(y - \varepsilon), \psi(y + \varepsilon))$ . So all but finitely many  $y_n$  are inside  $(y - \varepsilon, y + \varepsilon)$ . So  $y_n \rightarrow y$ . That  $y_n \rightarrow y$  implies  $x_n \rightarrow x$  is proved in a similar way.

Case 2:  $x = \pm\infty$ . We consider  $x = +\infty$  only; the other case is similar. Note that if  $0 < \varepsilon < b - a$ , then  $B_{[a,b]}(b, \varepsilon) = (b - \varepsilon, b]$ . If  $x_n \rightarrow +\infty$ , then for each  $0 < \varepsilon < b - a$ , all but finitely many  $x_n$  are  $> \psi(b - \varepsilon)$ . So all but finitely many  $y_n$  are inside  $(b - \varepsilon, b]$ . This proves  $y_n \rightarrow b$ . Conversely, if  $y_n \rightarrow b$ , then for each  $A \in \mathbb{R}$ , all but finitely many  $y_n$  are inside  $(\varphi(A), b]$  and hence  $> \varphi(A)$ . So all but finitely many  $x_n$  are  $> A$ .  $\square$

**Convention 2.70.** Unless otherwise stated, a metric on  $\overline{\mathbb{R}}$  is one that makes Def. 2.67 true, for instance  $\varphi^* d_{[a,b]}$  in Thm. 2.69. Unless otherwise stated, we do NOT view  $\mathbb{R}$  (or any subset of  $\mathbb{R}$ ) as a metric subspace of  $\overline{\mathbb{R}}$ . Namely, we do not follow Convention 2.15 for  $\mathbb{R} \subset \overline{\mathbb{R}}$ , or more generally for  $\mathbb{R}^N \subset \overline{\mathbb{R}}^N$ . Instead, we choose Euclidean metrics on  $\mathbb{R}^N$ , following Convention 2.8.

The main reason for not following Convention 2.15 here is that metrics on  $\overline{\mathbb{R}}$  are all bounded (by Prop. 3.7). Thus, every subset of  $\mathbb{R}$  is bounded if we view  $\mathbb{R}$  as a metric subspace of  $\overline{\mathbb{R}}$ . However, we want a subset of  $\mathbb{R}$  to be bounded precisely when it is contained in  $[a, b]$  for some  $-\infty < a < b < +\infty$ . (Recall also Def. 1.36.)

After learning topological spaces, we shall forget about the metrics on  $\overline{\mathbb{R}}$  and only care about its topology. (See Conv. 7.18.)

**Remark 2.71.** By Thm. 2.69, the properties of  $[a, b]$  about convergence of sequences and inequalities can be transported to  $\overline{\mathbb{R}}$ , for example:

1. If  $(x_n), (y_n)$  are sequences in  $\overline{\mathbb{R}}$  converging to  $A, B \in \overline{\mathbb{R}}$ , and if  $x_n \leq y_n$  for all  $n$ , then  $A \leq B$ .
2. **Squeeze theorem:** Suppose that  $(x_n), (y_n), (z_n)$  are sequences in  $\overline{\mathbb{R}}$ ,  $x_n \leq y_n \leq z_n$  for all  $n$ , and  $x_n$  and  $z_n$  both converge to  $A \in \overline{\mathbb{R}}$ . Then  $y_n \rightarrow A$ .
3. Prop. 2.23 also holds for  $[-\infty, +\infty] = \overline{\mathbb{R}}$ : if  $(x_n)$  is an increasing resp. decreasing sequence in  $\overline{\mathbb{R}}$ , then  $\lim_n x_n$  exists in  $\overline{\mathbb{R}}$  and equals  $\sup_n x_n$  resp.  $\inf_n x_n$ .

We will see more examples when studying  $\limsup$  and  $\liminf$  in the future.

We have shown that there is a metric on  $\overline{\mathbb{R}}$  which defines the convergence in Def. 2.67. However, there is no standard choice of such a metric on  $\overline{\mathbb{R}}$ . Even worse, two possible choices of metrics might not be equivalent: Let  $\varphi, \psi : \overline{\mathbb{R}} \rightarrow [0, 1]$  be a strictly increasing bijections where  $\psi \circ \varphi^{-1} : [0, 1] \rightarrow [0, 1]$  is  $x \mapsto x^2$ . Then by Exe. 2.65,  $\varphi^*d_{[0,1]}$  and  $\psi^*d_{[0,1]}$  are non-equivalent but topologically equivalent metrics on  $\overline{\mathbb{R}}$ . This is the first example that metrics are not convenient for the description of convergence. When studying the convergence in  $\overline{\mathbb{R}}$ , thinking about metrics is distracting. In the future, we will see a better notion for the study of convergence: the notion of topological spaces.

We end this section with a generalization of Thm. 2.69.

**Theorem 2.72.** Let  $\varphi$  be a strictly increasing bijection in one of the following forms

$$\begin{array}{ll} [a, b] \rightarrow [c, d] & (a, b) \rightarrow (c, d) \\ (a, b] \rightarrow (c, d] & [a, b) \rightarrow [c, d) \end{array}$$

where  $-\infty \leq a \leq b \leq +\infty$  and  $-\infty \leq c \leq d \leq +\infty$ . Then  $\varphi$  is a homeomorphism, i.e., if  $(x_n)$  and  $x$  are in the domain, then  $x_n \rightarrow x$  iff  $\varphi(x_n) \rightarrow \varphi(x)$  (in the sense of Def. 2.67).

*Proof.* The case  $a = b$  is obvious. So we consider  $a < b$ , and hence  $c < d$ . We consider the left-open-right-closed case for example. The other cases are treated in a similar way. If the theorem can be proved for  $(-\infty, +\infty] \rightarrow (c, d]$ , then it can also be proved  $(-\infty, +\infty] \rightarrow (a, b]$ . By composing the inverse of the second map with the first map, we see that the theorem holds for  $(a, b] \rightarrow (c, d]$ .

Let us consider  $\varphi : (-\infty, +\infty] \rightarrow (c, d]$ .  $\varphi$  can be extended to a strictly increasing bijection  $\varphi : \overline{\mathbb{R}} \rightarrow [c, d]$  by letting  $\varphi(-\infty) = c$ . It suffices to prove that this  $\varphi$  is a homeomorphism. When  $-\infty < c < d < +\infty$ , then the theorem holds by Thm. 2.69. If one of  $c, d$  is  $\pm\infty$ , the same argument as in the proof of Thm. 2.69 proves that  $\varphi$  is a homeomorphism. We leave it to the readers to fill in the details.  $\square$

## 2.6 Problems and supplementary material

**Definition 2.73.** Let  $A$  be a subset of  $\mathbb{R}$  satisfying  $x + y \in A$  for all  $x, y \in A$ . (Or more generally, let  $A$  be an abelian semigroup.) We say that a function  $f : A \rightarrow \mathbb{R}$  is **subadditive** if for every  $x, y \in A$  we have  $f(x + y) \leq f(x) + f(y)$ .

**Problem 2.1.** Consider the following increasing functions:

$$\begin{aligned} f_1 : \mathbb{R}_{\geq 0} &\rightarrow [0, 1) & f_1(x) &= \frac{x}{1+x} \\ f_2 : \mathbb{R}_{\geq 0} &\rightarrow [0, 1] & f_2(x) &= \min\{x, 1\} \end{aligned}$$

Prove that they are subadditive functions.

**Problem 2.2.** Let  $f : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$  be an increasing subadditive function satisfying the following conditions:

- (1)  $f^{-1}(0) = \{0\}$ .
- (2) For any  $(x_n)_{n \in \mathbb{Z}_+}$  in  $\mathbb{R}_{\geq 0}$  we have  $x_n \rightarrow 0$  iff  $f(x_n) \rightarrow 0$ .

Let  $(X, d)$  be a metric space. Define

$$\delta : X \times X \rightarrow [0, A) \quad \delta(x, y) = f \circ d(x, y)$$

Prove that  $\delta$  is a metric, and that  $\delta$  and  $d$  are topologically equivalent.

**Proposition 2.74.** Let  $(X, d)$  be a metric space. Then there is a bounded metric  $\delta$  on  $X$  such that  $d$  and  $\delta$  are topologically equivalent.

*Proof.* Let  $f$  be either  $f_1$  or  $f_2$  defined in Pb. 2.1. Then  $f$  satisfies the assumptions in Pb. 2.2. So  $\delta = f \circ d$  is a desired metric due to Pb. 2.2. We write down the formulas explicitly:

$$\delta_1(x, y) = \frac{d(x, y)}{1 + d(x, y)} \quad \delta_2(x, y) = \min\{d(x, y), 1\}$$

□

**Problem 2.3.** Let  $(X_i, d_i)_{i \in \mathbb{Z}_+}$  be a sequence of metric spaces. Assume that  $d_i \leq 1$  for each  $i$ . Let  $S = \prod_{i \in \mathbb{Z}_+} X_i$ . For each elements  $f = (f(i))_{i \in \mathbb{Z}_+}$  and  $g = (g(i))_{i \in \mathbb{Z}_+}$  of  $S$ , define

$$d(f, g) = \sup_{i \in \mathbb{Z}_+} \frac{d_i(f(i), g(i))}{i} \tag{2.14}$$

Prove that  $d$  is a metric on  $S$ . Let  $f_n = (f_n(i))_{i \in \mathbb{Z}_+}$  be a sequence in  $S$ . Let  $g \in S$ . Prove that the following are equivalent:

(a)  $\lim_{n \rightarrow \infty} f_n = g$  under the metric  $d$ .

(b)  $f_n$  **converges pointwisely** to  $g$ , namely,  $\lim_{n \rightarrow \infty} f_n(i) = g(i)$  for every  $i \in \mathbb{Z}_+$ .

**Remark 2.75.** The above problem gives our first non-trivial example of function spaces as metric spaces, where the domain of functions is a countable set. After learning series, the readers can check that

$$\delta(f, g) = \sum_{i \in \mathbb{Z}_+} 2^{-i} d_i(f(i), g(i)) \quad (2.15)$$

also defines a metric, and that (a) (with  $d$  replaced by  $\delta$ ) and (b) are equivalent. So  $\delta$  and  $d$  (defined by (2.14)) induce the same topology on  $X$ , called the **pointwise convergence topology** or simply **product topology**. Unfortunately, if the index set  $\mathbb{Z}_+$  is replaced by an uncountable set, there is in general no metric inducing the product topology. We will prove this in Pb. 7.9.

★ **Problem 2.4.** Let  $X = \bigsqcup_{\alpha \in \mathcal{A}} X_\alpha$  be a disjoint union of metric spaces  $(X_\alpha, d_\alpha)$ . Assume that  $d_\alpha \leq 1$  for all  $i$ . For each  $x, y \in X$ , define

$$d(x, y) = \begin{cases} d_\alpha(x, y) & \text{if } x, y \in X_\alpha \text{ for some } \alpha \in \mathcal{A} \\ \frac{1}{2} & \text{otherwise} \end{cases}$$

1. Prove that  $d$  defines a metric on  $X$ .
2. Choose  $(x_n)_{n \in \mathbb{Z}_+}$  in  $X$  and  $x \in X$ . What does  $\lim_{n \rightarrow \infty} x_n = x$  mean in terms of the convergence in each  $X_\alpha$ ?

Think about the question: Let  $X$  be a set. For each  $x, y \in X$  define  $d(x, y) = 0$  if  $x = y$ , and  $d(x, y) = 1$  if  $x \neq y$ . What does convergence in  $(X, d)$  mean?

## 3 Sequential compactness and completeness

### 3.1 Sequential compactness

#### 3.1.1 Basic properties of sequentially compact spaces

**Definition 3.1.** Let  $X$  be a metric space. We say that  $X$  is **sequentially compact** if every sequence in  $X$  has a subsequence converging to some point of  $X$ .

The notion of sequential compactness is extremely useful for finding solutions in an analysis problem. In general, suppose we want to find a point  $x \in X$  which makes a property  $P(x)$  to be true. Suppose that we can find an “approximate solution”, i.e. an  $y \in X$  such that  $P(y)$  is close to being true. Thus, we can find a sequence  $(x_n)$  in  $X$  such that  $P(x_n)$  is closer and closer to being true when  $n \rightarrow \infty$ . Now, if  $X$  is sequentially compact, then  $(x_n)$  has a subsequence  $(x_{n_k})$  converging to  $x \in X$ . Then  $P(x)$  is true, and hence  $x$  is a solution for the problem. (See also Sec. 2.1.) Let us see an explicit example:

**Lemma 3.2 (Extreme value theorem).** *Let  $X$  be a sequentially compact metric space. Let  $f : X \rightarrow \mathbb{R}$  be a continuous function. Then  $f$  attains its maximum and minimum at points of  $X$ . In particular,  $f(X)$  is a bounded subset of  $\mathbb{R}$ .*

This extremely important result is the main reason for introducing sequentially compact spaces. We call this a lemma, since we will substantially generalize this result later. (See Exe. 3.6.)

Note that the **boundedness** of subsets of  $\mathbb{R}$  (or more generally, of  $\mathbb{R}^N$ ) is always understood under the Euclidean metric of  $\mathbb{R}$ , not under any metric of  $\overline{\mathbb{R}}$  or  $\overline{\mathbb{R}}^N$ . (Recall Convention 2.70.)

*Proof.* We show that  $f$  attains its maximum on  $X$ . The proof for minimum is similar. Let  $A = \sup f(X)$ . Then  $A \in (-\infty, +\infty]$ . If  $A < +\infty$ , then for each  $n \in \mathbb{Z}_+$  there is  $x_n \in X$  such that  $A - 1/n < f(x_n) \leq A$  (since  $A - 1/n$  is not an upper bound of  $f(X)$ ). If  $A = +\infty$ , then for each  $n$  there is  $x_n \in X$  such that  $f(x_n) > n$ . In either case, we have a sequence  $(x_n)$  in  $X$  such that  $f(x_n) \rightarrow A$  in  $\overline{\mathbb{R}}$ .

Since  $X$  is sequentially compact,  $(x_n)$  has a subsequence  $(x_{n_k})_{k \in \mathbb{Z}_+}$  converging to some  $x \in X$ . Now, consider  $f$  as a map  $f : X \rightarrow \overline{\mathbb{R}}$ , which is continuous (cf. Exp. 2.51). Since  $f(x_n) \rightarrow A$ , its subsequence  $f(x_{n_k})$  also converges to  $A$ . But since  $x_{n_k} \rightarrow x$  and  $f$  is continuous at  $x$ , we have  $A = f(x)$ . So  $f$  attains its maximum at  $x$ . Since  $f(X) \subset \mathbb{R}$ , we have  $A \in \mathbb{R}$ .  $\square$

The following are some elementary examples of sequential compactness:

**Exercise 3.3.** Show that finite unions of sequentially compact spaces is sequentially compact. (In particular, a finite set is sequentially compact.)

More precisely, let  $X$  be a metric space. Assume  $X = A_1 \cup \cdots \cup A_N$  where each metric subspace  $A_i$  is sequentially compact. Show that  $X$  is sequentially compact.

**Proposition 3.4.** Let  $X_1, \dots, X_N$  be sequentially compact metric spaces. Then  $X = X_1 \times \dots \times X_N$  is sequentially compact.

*Proof.* Since  $X = (X_1 \times \dots \times X_{N-1}) \times X_N$ , by induction, it suffices to assume  $N = 2$ . So we write  $X = A \times B$  where  $A, B$  are sequentially compact. Let  $(a_n, b_n)$  be a sequence in  $X$ . Since  $A$  is sequentially compact,  $(a_n)$  has a convergent subsequence  $(a_{n_k})$ . Since  $B$  is sequentially compact,  $(b_{n_k})$  has a convergent subsequence  $(b_{n_{k_l}})$ . So  $(a_{n_{k_l}}, b_{n_{k_l}})$  is a convergent subsequence of  $(a_n, b_n)$ .  $\square$

**Proposition 3.5.** Let  $f : X \rightarrow Y$  be a continuous map of metric spaces. Assume that  $X$  is sequentially compact. Then  $f(X)$ , as a metric subspace of  $Y$ , is sequentially compact.

*Proof.* Choose any sequence  $(y_n)$  in  $f(X)$ . We can write  $y_n = f(x_n)$  where  $x_n \in X$ . Since  $X$  is sequentially compact,  $(x_n)$  has a subsequence  $(x_{n_k})$  converging to some  $x \in X$ . Since  $f$  is continuous,  $y_{n_k} = f(x_{n_k})$  converges to  $f(x)$ .  $\square$

**Exercise 3.6.** Prove that if  $Y$  is a sequentially compact subset of  $\mathbb{R}$ , then  $\sup Y \in Y$  and  $\inf Y \in Y$ . Therefore, Prop. 3.5 generalizes Lem. 3.2.

**Proposition 3.7.** Let  $X$  be a sequentially compact metric space. Then  $X$  is bounded under its metric  $d$ .

*Proof.* Choose any  $p \in X$ . The function  $d_p : x \in X \mapsto d(x, p) \in \mathbb{R}_{\geq 0}$  is continuous by Exp. 2.58. So, by Lem. 3.2,  $d_p$  is bounded by some  $0 < R < +\infty$ . So  $X = \overline{B_X(p, R)} \subset B_X(p, 2R)$ .  $\square$

### 3.1.2 Limits inferior and superior, and Bolzano-Weierstrass

The goal of this subsection is to prove that closed intervals are sequentially compact.

**Definition 3.8.** Let  $(x_n)$  be a sequence in a metric space  $X$ . We say that  $x \in X$  is a **cluster point** of  $(x_n)$ , if  $(x_n)$  has a subsequence  $(x_{n_k})$  converging to  $x$ .

Warning: In a general topological space, the cluster points of a sequence will be defined in a different way. (See Pb. 7.2 and Rem. 7.99.)

**Definition 3.9.** Let  $(x_n)$  be a sequence in  $\overline{\mathbb{R}}$ . Define

$$\alpha_n = \inf\{x_k : k \geq n\} \quad \beta_n = \sup\{x_k : k \geq n\} \quad (3.1)$$

It is clear that  $\alpha_n \leq x_n \leq \beta_n$ , that  $(\alpha_n)$  is increasing and  $(\beta_n)$  is decreasing. Define

$$\liminf_{n \rightarrow \infty} x_n = \sup\{\alpha_n : n \in \mathbb{Z}_+\} = \lim_{n \rightarrow \infty} \alpha_n \quad (3.2a)$$

$$\limsup_{n \rightarrow \infty} x_n = \inf\{\beta_n : n \in \mathbb{Z}_+\} = \lim_{n \rightarrow \infty} \beta_n \quad (3.2b)$$

(cf. Rem. 2.71), called respectively the **limit inferior** and the **limit superior** of  $(x_n)$ .

**Remark 3.10.** Let  $(x_n), (y_n)$  be sequences in  $\overline{\mathbb{R}}$ . Suppose that  $x_n \leq y_n$  for every  $n$ . It is clear that

$$\liminf_{n \rightarrow \infty} x_n \leq \limsup_{n \rightarrow \infty} x_n \quad \liminf_{n \rightarrow \infty} x_n \leq \liminf_{n \rightarrow \infty} y_n \quad \limsup_{n \rightarrow \infty} x_n \leq \limsup_{n \rightarrow \infty} y_n$$

**Theorem 3.11.** Let  $(x_n)$  be a sequence in  $\overline{\mathbb{R}}$ , and let  $S$  be the set of cluster points of  $(x_n)$ . Then  $\liminf_{n \rightarrow \infty} x_n$  and  $\limsup_{n \rightarrow \infty} x_n$  belong to  $S$ . They are respectively the minimum and the maximum of  $S$ .

In particular, every sequence in  $\overline{\mathbb{R}}$  has at least one cluster point.

*Proof.* We use the notations in Def. 3.9. Let  $A = (3.2a)$  and  $B = (3.2b)$ . If  $x \in S$ , pick a subsequence  $(x_{n_k})$  converging to  $x$ . Since  $\alpha_{n_k} \leq x_{n_k} \leq \beta_{n_k}$ , we have  $A \leq x \leq B$  by Rem. 2.71. It remains to show that  $A, B \in S$ . We prove  $B \in S$  by constructing a subsequence  $(x_{n_k})$  converging to  $B$ ; the proof of  $A \in S$  is similar.

Consider first of all the special case that  $(x_n)$  is bounded, i.e., is inside  $[a, b] \subset \mathbb{R}$ . Choose an arbitrary  $n_1 \in \mathbb{Z}_+$ . Suppose  $n_1 < \dots < n_k$  has been constructed. By the definition of  $\beta_{1+n_k}$ , there is  $n_{k+1} \geq 1 + n_k$  such that  $x_{n_{k+1}}$  is close to  $\beta_{1+n_k}$ , say

$$\beta_{1+n_k} - \frac{1}{k} < x_{n_{k+1}} \leq \beta_{1+n_k} \quad (3.3)$$

Since the left most and the right most of (3.3) both converge to  $B$  as  $k \rightarrow \infty$ , by Squeeze theorem (Cor. 2.48) we conclude  $\lim_k x_{n_k} = B$ .

In general, by Lem. 2.68 and Thm. 2.72, there is an increasing (i.e. order-preserving) homeomorphism (i.e. topology-preserving map)  $\varphi : \overline{\mathbb{R}} \rightarrow [0, 1]$ . Then  $\varphi(\beta_n) = \sup\{\varphi(x_k) : k \geq n\}$  (cf. Exe. 3.13) and  $\varphi(B) = \lim_n \varphi(\beta_n)$ . So  $\varphi(B) = \limsup_n \varphi(x_n)$ . By the above special case,  $(\varphi(x_n))$  has a subsequence  $(\varphi(x_{n_k}))$  converging to  $\varphi(B)$ . So  $(x_{n_k})$  converges to  $B$ .  $\square$

**Remark 3.12.** One can also prove the above general case directly using a similar idea as in the special case. And you are encouraged to do so! (Pay attention to the case  $B = \pm\infty$ .)

The proof given above belongs to a classical proof pattern: To prove that a space  $X$  satisfies some property, one first prove it in a convenient case. Then, in the general case, one finds an “isomorphism” (i.e. “equivalence” in a suitable sense)  $\varphi : X \rightarrow Y$  where  $Y$  is in the convenient case. Then the result on  $Y$  can be translated via  $\varphi^{-1}$  to  $X$ , finishing the proof.

For example, to solve a linear algebra problem about linear maps between finite-dimensional vector spaces  $V, W$ , one first proves it in the special case that  $V = \mathbb{F}^m$  and  $W = \mathbb{F}^n$ . Then, the general case can be translated to the special case via an equivalence as in Exp. 1.21.  $\square$

**Exercise 3.13.** Let  $X, Y$  be posets. Let  $\varphi : X \rightarrow Y$  be an increasing bijection whose inverse is also increasing. (Namely,  $\varphi$  induces an equivalence of posets). Suppose  $E \subset X$  has supremum  $\sup E$ . Explain why  $\varphi(E)$  has supremum  $\varphi(\sup E)$ .

It is now fairly easy to prove the famous

**Theorem 3.14** (Bolzano-Weierstrass). *Let  $[a_1, b_1], \dots, [a_N, b_N]$  be closed intervals in  $\overline{\mathbb{R}}$ . Then  $[a_1, b_1] \times \dots \times [a_N, b_N]$  is sequentially compact.*

*Proof.* By Prop. 3.4, it suffices to assume  $N = 1$ . Write  $a_1 = a, b_1 = b$ . Let  $(x_n)$  be a sequence in  $[a, b]$ . By Thm. 3.11,  $(x_n)$  has a subsequence  $(x_{n_k})$  converging to some  $x \in \overline{\mathbb{R}}$ . (E.g.  $x = \limsup_n x_n$ .) Since  $a \leq x_{n_k} \leq b$ , we have  $a \leq x \leq b$  by Rem. 2.71.  $\square$

Bolzano-Weierstrass theorem illustrates why we sometimes prefer to work with  $\overline{\mathbb{R}}$  instead of  $\mathbb{R}$ :  $\overline{\mathbb{R}}$  is sequentially compact, while  $\mathbb{R}$  is not. That every sequence has limits superior and inferior in  $\overline{\mathbb{R}}$  but not necessarily in  $\mathbb{R}$  is closely related to this fact. In the language of point-set topology,  $\overline{\mathbb{R}}$  is a **compactification** of  $\mathbb{R}$ .

Bolzano-Weierstrass theorem (restricted to  $\mathbb{R}^N$ ) will be generalized to **Heine-Borel theorem**, which says that a subset of  $\mathbb{R}^N$  is sequentially compact iff it is bounded and closed (cf. Def. 3.26 for the definition of closed subsets). See Thm. 3.54.

### 3.1.3 A criterion for convergence in sequentially compact spaces

At the end of Sec. 2.3, we have raised the following question: Suppose that  $(x_n)$  is a bounded sequence in a metric space  $X$  such that any two convergent subsequences converge to the same point. Does  $(x_n)$  converge?

When  $X$  is sequentially compact,  $(x_n)$  is automatically bounded due to Prop. 3.7. The answer to the above question is yes:

**Theorem 3.15.** *Let  $X$  be a sequentially compact metric space. Let  $(x_n)$  be a sequence in  $X$ . Then the following are equivalent.*

- (1) *The sequence  $(x_n)$  converges in  $X$ .*
- (2) *Any two convergent subsequences of  $(x_n)$  converge to the same point. In other words,  $(x_n)$  has only one cluster point.*

*Proof.* (1) $\Rightarrow$ (2): By Prop. 2.36.

(2) $\Rightarrow$ (1): Assume that  $(x_n)$  has at most one cluster point. Since  $X$  is sequentially compact,  $(x_n)$  has at least one cluster point  $x \in X$ . We want to prove  $\lim_{n \rightarrow \infty} x_n = x$ . Suppose not. Then there exists  $\varepsilon > 0$  such that for every  $N \in \mathbb{Z}_+$  there is  $n \geq N$  such that  $d(x_n, x) \geq \varepsilon$ . Thus, one can inductively construct a subsequence  $(x_{n_k})$  of  $(x_n)$  such that  $d(x_{n_k}, x) \geq \varepsilon$  for all  $k$ . Since  $X$  is sequentially compact,  $(x_{n_k})$  has a subsequence  $x'_n$  converging to  $x' \in X$ . So  $d(x'_n, x) \geq \varepsilon$  for all  $n$ . Since the function  $y \in X \mapsto d(y, x)$  is continuous (Exp. 2.58), we have  $\lim_{n \rightarrow \infty} d(x'_n, x) = d(x', x)$ . This proves that  $d(x', x) \geq \varepsilon > 0$ . However,  $x', x$  are both cluster points of  $(x_n)$ , and so  $x = x'$ . This gives a contradiction.  $\square$

**Remark 3.16.** Thm. 3.15 can be used in the following way. Suppose that we want to prove that a given sequence  $(x_n)$  in a sequentially compact space  $X$  converges to  $x$ . Then it suffices to prove that if  $(x'_n)$  is a subsequence of  $(x_n)$  converging to some  $y \in X$ , then  $y = x$ . This is sometimes easier to prove than directly proving the convergence of  $(x_n)$ . We will use this strategy in the proof of L'Hôpital's rule, for example.

**Corollary 3.17.** *Let  $(x_n)$  be a sequence in  $\mathbb{R}^N$ . The following are equivalent.*

- (1) *The sequence  $(x_n)$  converges in  $\mathbb{R}^N$ .*
- (2) *The sequence  $(x_n)$  is bounded. Moreover, any two convergent subsequences of  $(x_n)$  converge to the same point of  $\mathbb{R}^N$ .*

*Proof.* (1) $\Rightarrow$ (2): By Prop. 2.33 and 2.36.

(2) $\Rightarrow$ (1): Assume (2). Since  $(x_n)$  is bounded, it can be contained in  $X = I_1 \times \cdots \times I_N$  where each  $I_i$  is a closed interval in  $\mathbb{R}$ . Clearly, any two cluster points of  $(x_n)$  are inside  $X$ , and are equal by (2). By Bolzano-Weierstrass,  $X$  is sequentially compact. Thus, by Thm. 3.15,  $(x_n)$  converges in  $X$  and hence in  $\mathbb{R}^N$ .  $\square$

**Corollary 3.18.** *The following are true.*

1. *Let  $(x_n)$  be a sequence in  $\overline{\mathbb{R}}$ . Then  $(x_n)$  converges in  $\overline{\mathbb{R}}$  iff  $\limsup_{n \rightarrow \infty} x_n$  equals  $\liminf_{n \rightarrow \infty} x_n$ .*
2. *Let  $(x_n)$  be a sequence in  $\mathbb{R}$ . Then  $(x_n)$  converges in  $\mathbb{R}$  iff  $\limsup_{n \rightarrow \infty} x_n$  equals  $\liminf_{n \rightarrow \infty} x_n$  and  $(x_n)$  is bounded.*

Note that if  $(x_n)$  converges in  $\overline{\mathbb{R}}$ , we must have  $\lim x_n = \limsup x_n = \liminf x_n$  by Thm. 3.11.

*Proof.* 1. Let  $A = \liminf x_n$  and  $B = \limsup x_n$ . Let  $S$  be the set of cluster points of  $(x_n)$ . By Thm. 3.11,  $A = \min S, B = \max S$ . So  $A = B$  iff  $S$  has only one element. This is equivalent to the convergence of  $(x_n)$  in  $\overline{\mathbb{R}}$  due to Thm. 3.15 (since  $\overline{\mathbb{R}}$  is sequentially compact by Bolzano-Weierstrass.)

2. If  $(x_n)$  converges, then  $A = B$  by part 1. And  $(x_n)$  is bounded due to Prop. 2.33. Conversely, if  $A = B$  and if  $(x_n)$  is bounded, say  $\alpha \leq x_n \leq \beta$  for all  $n$  where  $-\infty < \alpha < \beta < +\infty$ . Then  $\alpha \leq A \leq B \leq \beta$ . So  $A, B \in \mathbb{R}$ . By part 1,  $(x_n)$  converges to  $A \in \mathbb{R}$ .  $\square$

## 3.2 Outlook: sequentially compact function spaces

In Sec. 2.1, we mentioned that metric spaces and (more generally) point-set topology were introduced by mathematicians in order to study (typically infinite dimensional) function spaces with the help of the geometric intuition of  $\mathbb{R}^N$ . Now we have learned a couple of important results about sequentially compact spaces. But we have not met any example arising from function spaces. So let me show one example to the curious readers: The product space  $[0, 1]^{\mathbb{Z}_+}$ , equipped with the metric defined in Pb. 2.3, is sequentially compact. We will prove this result at the end of this chapter. (Indeed, we will prove a slightly more general version. See Thm. 3.53.) This is a famous result, not only because it has many important applications (some of which will be hinted at in this section), but also because its proof uses the clever “diagonal method”.

Moreover, we will later prove an even more surprising fact: every sequentially compact metric space is homeomorphic to a closed subset of  $[0, 1]^{\mathbb{Z}_+}$ . (See Thm. 8.47.) Thus, all sequentially compact metric spaces can be constructed explicitly, in some sense.

The readers may still complain that functions on  $\mathbb{Z}_+$  are very different from those we often see and use in analysis and (especially) in differential equations: We are ultimately interested in functions on  $\mathbb{R}$  or on  $[a, b]$ , but not on countable sets. This is correct. But  $[0, 1]^{\mathbb{Z}_+}$  (and its closed subsets) are in fact very helpful for the study of spaces of functions on  $\mathbb{R}$  and on  $[a, b]$ . In this course, we shall learn two major examples that the sequential compactness of  $[0, 1]^{\mathbb{Z}_+}$  helps with:

1.  $A = \mathbb{Q} \cap [a, b]$  is a countable dense subset of  $[a, b]$ . Thus, if we let  $C([a, b])$  denote the set of continuous  $\mathbb{R}$ -functions on  $[a, b]$ , then the restriction map  $f \in C([a, b]) \mapsto f|_A \in \mathbb{R}^A$  is injective. In many applications, we are interested in a subset  $\mathcal{X} \subset C([a, b])$  of uniformly bounded functions, say all  $f \in \mathcal{X}$  take values in  $[-1, 1]$ . Then we have an injective map

$$\Phi : \mathcal{X} \rightarrow [-1, 1]^A \quad f \mapsto f|_A$$

If  $\mathcal{X}$  satisfies a condition called “**equicontinuous**”, then a sequence  $f_n$  in  $\mathcal{X}$  converges *uniformly* to  $f \in C([a, b])$  iff  $f_n|_A$  converges *pointwisely* to  $f|_A$ . (See Rem. 3.61.) Thus, from the sequential compactness of  $[-1, 1]^A$  under pointwise convergence topology, one concludes that every sequence in  $\mathcal{X}$  has a subsequence converging uniformly in  $C([a, b])$ . This remarkable sequential compactness result on (the closure of)  $\mathcal{X}$  is called **Arzelà-Ascoli theorem**, and will be used to prove the fundamental Peano existence theorem in ordinary differential equations. We also see that the fact that  $[a, b]$  has a countable dense subset  $A$  plays a crucial role. This property of metric spaces is called “**separable**” and will be studied later.

2. **Fourier series** are powerful for the study of partial differential equations. A continuous function  $f : [-\pi, \pi] \rightarrow \mathbb{C}$  satisfying  $f(-\pi) = f(\pi)$  has Fourier

series expansion  $f(x) = \sum_{n \in \mathbb{Z}} a_n e^{inx}$  where  $a_n \in \mathbb{C}$ . However, for the sake of studying differential equations, one needs to consider series  $\sum_{n \in \mathbb{Z}} a_n e^{inx}$  converging to a function much worse than a continuous function. For example, in the study of integral equations (which are closely related to certain partial differential equations), Hilbert and Schmidt discovered that one has to consider all  $f(x) = \sum_{n \in \mathbb{Z}} a_n e^{inx}$  satisfying  $\sum_n |a_n|^2 \leq 1$ . Therefore, one lets  $\overline{B} = \{z \in \mathbb{C} : |z| \leq 1\}$  and considers  $\hat{f} : n \in \mathbb{Z} \mapsto a_n \in \mathbb{C}$  as an element of  $\overline{B}^{\mathbb{Z}}$ . The sequential compactness of  $\overline{B}^{\mathbb{Z}}$  helps one find the  $\hat{f}$  such that the corresponding  $f(x) = \sum_n \hat{f}(n) \cdot e^{inx}$  is a desired solution of the integral equation.

### 3.3 Complete metric spaces and Banach spaces

In this section, we let  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ , and assume that all vector spaces are over  $\mathbb{F}$ .

#### 3.3.1 Cauchy sequences and complete metric spaces

**Definition 3.19.** A sequence  $(x_n)$  in a metric space  $X$  is called a **Cauchy sequence**, if:

- For every  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that for all  $m, n \geq N$  we have  $d(x_m, x_n) < \varepsilon$ .

Here, “ $\varepsilon > 0$ ” can mean either “ $\varepsilon \in \mathbb{R}_{>0}$ ” or “ $\varepsilon \in \mathbb{Q}_{>0}$ ”. The choice of this meaning does not affect the definition. The above definition can be abbreviated to “for every  $\varepsilon > 0$ , we have  $d(x_m, x_n) < \varepsilon$  for sufficiently large  $m, n$ ”.

**Remark 3.20.** It is an easy consequence of triangle inequality that  $(x_n)$  is a Cauchy sequence iff

- For every  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  we have  $d(x_n, x_N) < \varepsilon$ .

Also, it is clear that every Cauchy sequence is bounded.

**Proposition 3.21.** Every convergent sequence in a metric space  $X$  is a Cauchy sequence.

*Proof.* Assume  $(x_n)$  converges to  $x$  in  $X$ . Then for every  $\varepsilon > 0$  there is  $N \in \mathbb{Z}_+$  such that  $d(x, x_n) < \varepsilon/2$  for all  $n \geq N$ . Since this is true for every  $m \geq N$ , we have  $d(x_m, x_n) \leq d(x, x_n) + d(x, x_m) < \varepsilon/2 + \varepsilon/2 = \varepsilon$ .  $\square$

**Definition 3.22.** A metric space  $X$  is called **complete** if every Cauchy sequence in  $X$  converges.

We have many examples of complete metric spaces:

**Theorem 3.23.** *If  $(x_n)$  is a Cauchy sequence in a metric space  $X$  with at least one cluster point, then  $(x_n)$  converges in  $X$ . Consequently, every sequentially compact metric space is complete.*

*Proof.* Let  $(x_n)$  be a Cauchy sequence in  $X$  with subsequence  $(x_{n_k})$  converging to  $x \in X$ . Let us show that  $x_n \rightarrow x$ .

Since  $(x_n)$  is Cauchy, for every  $\varepsilon > 0$  there is  $N \in \mathbb{Z}_+$  such that  $d(x_n, x_m) < \varepsilon/2$  for all  $m, n \geq N$ . Since  $x_{n_k} \rightarrow x$ , there is  $k \geq N$  such that  $d(x_{n_k}, x) < \varepsilon/2$ . Since  $n_k$  is strictly increasing over  $k$ , we have  $n_k \geq k$ . So  $n_k \geq N$ . So we can let  $m = n_k$ . This gives  $d(x_n, x_{n_k}) < \varepsilon/2$ . Therefore  $d(x_n, x) \leq d(x_n, x_{n_k}) + d(x_{n_k}, x) < \varepsilon$  for all  $n \geq N$ .  $\square$

**Example 3.24.** Let  $X = [a_1, b_1] \times \cdots \times [a_N, b_N]$  where each  $[a_i, b_i]$  is a closed interval in  $\mathbb{R}$ , then  $X$  is sequentially compact by Bolzano-Weierstrass. Thus, by Thm. 3.23,  $X$  is complete.

**Corollary 3.25.**  $\mathbb{R}^N$  and  $\mathbb{C}^N$  are complete (under the Euclidean metrics).

*Proof.* Since  $\mathbb{C}^N$  is isometrically isomorphic to  $\mathbb{R}^{2N}$ , it suffices to prove that  $\mathbb{R}^N$  is complete. Choose a Cauchy sequence  $(x_n)$  in  $\mathbb{R}^N$ . Since  $(x_n)$  is bounded,  $(x_n)$  is contained inside  $X = I_1 \times \cdots \times I_N$  where each  $I_i = [a, b]$  is in  $\mathbb{R}$ . By Exp. 3.24,  $X$  is complete. So  $(x_n)$  converges to some  $x \in X$ .  $\square$

**Definition 3.26.** We say that a subset  $A$  of a metric space  $X$  is **closed** if the following condition is true: For every sequence  $(x_n)$  in  $A$  converging to a point  $x \in X$ , we have  $x \in A$ .

Thus, the word “closed” here means “closed under taking limits”.

**Proposition 3.27.** *Let  $A$  be a metric subspace of a metric space  $X$ . Recall that the metric of  $A$  inherits from that of  $X$  (cf. Def. 2.14). Consider the statements:*

- (1)  $A$  is complete.
- (2)  $A$  is a closed subset of  $X$ .

*Then (1) $\Rightarrow$ (2). If  $X$  is complete, then (2) $\Rightarrow$ (1).*

*Proof.* First, assume that  $X$  is complete and (2) is true. Let  $(x_n)$  be a Cauchy sequence in  $A$ . Then it is a Cauchy sequence in  $X$ . So  $x_n \rightarrow x \in X$  because  $X$  is complete. So  $x \in A$  by the definition of closedness. This proves (1).

Next, we assume (1). Choose a sequence  $(x_n)$  in  $A$  converging to a point  $x \in X$ . By Prop. 3.21,  $(x_n)$  is a Cauchy sequence in  $X$ , and hence a Cauchy sequence in  $A$ . Since  $A$  is complete, there is  $a \in A$  such that  $x_n \rightarrow a$ . So we must have  $x = a$  because any sequence has at most one limit in a metric space. This proves  $x \in A$ . So (2) is proved.  $\square$

A similar result holds for sequential compactness. See Pb. 3.4.

**Example 3.28.** Let  $-\infty < a < b < +\infty$ . Then  $(a, b)$  is not complete (under the Euclidean metric), because  $(a, b)$  is not closed in the metric space  $\mathbb{R}$ . (For sufficiently large  $n$ ,  $b - 1/n$  is in  $(a, b)$ , but  $\lim_{n \rightarrow \infty} (b - 1/n) = b$  is not in  $b$ .)

**Example 3.29.** By Prop. 1.29, for each  $x \in \mathbb{R} \setminus \mathbb{Q}$ , we can choose an increasing sequence in  $\mathbb{Q}$  converging to  $x$ . So  $\mathbb{Q}$  is not closed in  $\mathbb{R}$ . So  $\mathbb{Q}$  is not complete under the Euclidean topology.

**Example 3.30.** Let  $X$  be a metric space. Let  $p \in X$  and  $0 \leq R < +\infty$ . Then  $\overline{B}_X(x, R)$  is a closed subset of  $X$ . Therefore, if  $X$  is complete, then  $\overline{B}_X(p, R)$  is complete by Prop. 3.27.

*Proof of closedness.* Let  $(x_n)$  be a sequence in  $\overline{B}(p, R)$  converging to  $x \in X$ . Then  $d(p, x_n) \leq R$ . Since the function  $y \in X \mapsto d(p, y) \in \mathbb{R}$  is continuous (Exp. 2.58), we have  $d(p, x) = \lim_{n \rightarrow \infty} d(p, x_n) \leq R$ . So  $x \in \overline{B}(p, R)$ .  $\square$

**Exercise 3.31.** Let  $d, \delta$  be two equivalent metrics on a set  $X$ . Show that a sequence  $(x_n)$  in  $X$  is Cauchy under  $d$  iff  $(x_n)$  is Cauchy under  $\delta$ .

Note that if, instead of assuming  $d, \delta$  are equivalent, we only assume that  $d, \delta$  are topologically equivalent. Then the above conclusion is not necessarily true:

**Exercise 3.32.** Find a non-complete metric  $\delta$  on  $\mathbb{R}$  topologically equivalent to the Euclidean metric.

### 3.3.2 Normed vector spaces and Banach spaces

A major application of complete metric spaces is to show that many series converge without knowing to what exact values these series converge. A typical example is the convergence of  $\sum_{n \in \mathbb{Z}_+} \sin(\sqrt{2}n)/n^2$  in  $\mathbb{R}$ . We are also interested in the convergence of series in function spaces, for instance: the uniform convergence of  $f(x) = \sum_{n \in \mathbb{Z}_+} \sin(\sqrt{2}nx^3)/n^2$  on  $\mathbb{R}$ ; a suitable convergence of the Fourier series  $\sum_{n \in \mathbb{Z}} a_n e^{inx}$ . But we cannot take sum in a general metric space since it has no vector space structures. Therefore, we need a notion which combines complete metric spaces with vector spaces. Banach spaces are such a notion.

**Definition 3.33.** Let  $V$  be a vector space over  $\mathbb{F}$  with zero vector  $0_V$ . A function  $\|\cdot\|: V \rightarrow \mathbb{R}_{\geq 0}$  is called a **norm** if for every  $u, v \in V$  and  $\lambda \in \mathbb{F}$ , the following hold:

- (Subadditivity)  $\|u + v\| \leq \|u\| + \|v\|$ .
- (Absolute homogeneity)  $\|\lambda v\| = |\lambda| \cdot \|v\|$ . In particular, (by taking  $\lambda = 0$ ) we have  $\|0_V\| = 0$ .
- If  $\|v\| = 0$  then  $v = 0_V$ .

We call  $(V, \|\cdot\|)$  (often abbreviated to  $V$ ) a **normed vector space**.

**Remark 3.34.** Let  $V$  be a vector space. If  $V$  is a normed vector space, then

$$d(u, v) = \|u - v\| \quad (3.4)$$

clearly defines a metric. (Note that triangle inequality follows from subadditivity.) Unless otherwise stated, we always assume that the metric of a normed vector space is defined by (3.4).

**Definition 3.35.** Let  $V$  be a normed vector space. We say that  $V$  is a **Banach space** if  $V$  is a complete metric space where the metric is the canonical one (3.4). If  $V$  is over the field  $\mathbb{C}$  (resp.  $\mathbb{R}$ ), we call  $V$  a **complex** (resp. **real**) **Banach space**.

**Example 3.36.** We always assume that the norm on  $\mathbb{F}^N$  is the **Euclidean norm**

$$\|(a_1, \dots, a_N)\| = \sqrt{|a_1|^2 + \dots + |a_N|^2} \quad (3.5)$$

The canonical metric it gives is the Euclidean metric. Thus, by Cor. 3.25,  $\mathbb{F}^N$  is a Banach space.

If  $(\lambda_n)$  is a sequence in  $\mathbb{F}$  converging to  $\lambda$ , and if  $(x_n)$  is a sequence in  $\mathbb{F}^N$  converging to  $x$ , then one can show that  $\lambda_n x_n$  converges to  $\lambda x$  by checking that each component of  $\lambda_n x_n$  converges to the corresponding component of  $\lambda x$ . This is due to Prop. 2.27. However, if  $(x_n)$  is in general a sequence in a normed vector space, this method fails. So we need a different argument:

**Proposition 3.37.** *Let  $V$  be a normed vector space. The following maps are continuous*

$$\begin{aligned} + : V \times V &\rightarrow V & (u, v) &\mapsto u + v \\ - : V \times V &\rightarrow V & (u, v) &\mapsto u - v \\ \times_{\mathbb{F}} : \mathbb{F} \times V &\rightarrow V & (\lambda, v) &\mapsto \lambda v \\ \|\cdot\| : V &\rightarrow \mathbb{R}_{\geq 0} & v &\mapsto \|v\| \end{aligned}$$

We didn't mention the continuity of the division map  $(\lambda, v) \in \mathbb{F}^\times \times V \mapsto \lambda^{-1}v$  since it follows from that of  $\times_{\mathbb{F}}$  and of the inversion map  $\lambda \mapsto \lambda^{-1}$  by Exp. 2.44.

*Proof.* One can check that the addition map, the subtraction map, and the last map  $\|\cdot\|$  are Lipschitz continuous.

Define metric  $d((\lambda, v), (\lambda', v')) = \max\{|\lambda - \lambda'|, \|v - v'\|\}$  on  $\mathbb{F} \times V$ . Then  $\mathbb{F} \times V$  is covered by open balls of the form  $B(0, r) = \{(\lambda, v) \in \mathbb{F} \times V : |\lambda| < r, \|v\| < r\}$ . Similar to the argument in (2.6), one uses subadditivity (i.e. triangle inequality) and absolute homogeneity to show that  $\times_{\mathbb{F}}$  has Lipschitz constant  $2r$  on  $B(0, r)$ . So  $\times_{\mathbb{F}}$  is continuous by Lem. 2.41 and 2.43.  $\square$

### 3.4 The Banach spaces $l^\infty(X, V)$ and $C(X, V)$

In this section, we let  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$  and assume that the vector spaces  $V$  are over  $\mathbb{F}$ . As the title suggests, in this section we shall introduce two important examples of Banach spaces: the space of uniformly bounded functions  $l^\infty(X, V)$  and its subspace of continuous functions  $C(X, V)$  (when  $X$  is a sequentially compact metric space). In order for these two spaces to be Banach spaces, we must assume that  $V$  is also Banach.

In application, the main examples are  $V = \mathbb{R}, \mathbb{C}, \mathbb{R}^N, \mathbb{C}^N$ . Indeed,  $C([a, b], \mathbb{R}^N)$  is one of the main examples of function spaces considered by Fréchet when he defined metric spaces. Therefore, the readers can assume that  $V$  is one of such spaces if they want to make life easier. Just keep in mind that we sometimes also consider the case where  $V$  itself is a function space.

**Definition 3.38.** Let  $X$  be a set and let  $V$  be a vector space. The set  $V^X$  is a vector space if we define for each  $f, g \in V^X$  and  $\lambda \in \mathbb{F}$ :

$$\begin{aligned} f + g : X &\rightarrow V & (f + g)(x) &= f(x) + g(x) \\ \lambda f : X &\rightarrow V & (\lambda f)(x) &= \lambda f(x) \end{aligned}$$

We also define the **absolute value function**

$$|f| : X \rightarrow \mathbb{R}_{\geq 0} \quad x \in X \mapsto \|f(x)\| \quad (3.6)$$

The symbol  $|f|$  is sometimes also written as  $\|f\|$  when it will not be confused with  $\|f\|_\infty$  or other norms of  $f$ .

**Definition 3.39.** Let  $X$  be a set and let  $V$  be a normed vector space. For each  $f \in V^X$ , define the  **$l^\infty$ -norm**

$$\|f\|_{l^\infty(X, V)} \equiv \|f\|_{l^\infty} \equiv \|f\|_\infty = \sup_{x \in X} \|f(x)\| \quad (3.7)$$

where  $\|f(x)\|$  is defined by the norm of  $V$ . Define the  **$l^\infty$ -space**

$$l^\infty(X, V) = \{f \in V^X : \|f\|_\infty < +\infty\} \quad (3.8)$$

which is a vector subspace of  $V^X$ . Then  $l^\infty(X, V)$  is a normed vector space under the  $l^\infty$ -norm. A function  $f : X \rightarrow V$  is called **uniformly bounded** if  $f \in l^\infty(X, V)$ .

**Exercise 3.40.** Prove that for every  $f, g \in V^X$  and  $\lambda \in \mathbb{F}$  we have

$$\begin{aligned} \|f + g\|_\infty &\leq \|f\|_\infty + \|g\|_\infty \\ \|\lambda f\|_\infty &= |\lambda| \cdot \|f\|_\infty \end{aligned} \quad (3.9)$$

(Note that clearly we have that  $\|f\|_\infty = 0$  implies  $f = 0$ .) Here, we understand  $0 \cdot (+\infty) = 0$ . Use these relations to verify that  $l^\infty(X, V)$  is a linear subspace of  $V^X$  (i.e. it is closed under addition and scalar multiplication) and that  $\|\cdot\|_\infty$  is a norm on  $l^\infty(X, V)$ .  $\square$

**Definition 3.41.** Let  $V$  be a normed vector space. We say that a sequence  $(f_n)$  in  $V^X$  **converges uniformly** to  $f \in V^X$  if  $\lim_{n \rightarrow \infty} \|f - f_n\|_\infty = 0$ . In this case, we write  $f_n \rightrightarrows f$ .

We say that  $(f_n)$  **converges pointwisely** to  $f \in V^X$  if for every  $x \in X$  we have  $\lim_{n \rightarrow \infty} f_n(x) = f(x)$ , i.e.  $\lim_{n \rightarrow \infty} \|f_n(x) - f(x)\| = 0$ .

The same definition will be applied to nets  $(f_\alpha)_{\alpha \in I}$  in  $V^X$  after learning net convergence in Sec. 5.2.  $\square$

In more details, the uniform convergence of  $f_n$  to  $f$  means that “for every  $\varepsilon > 0$  there is  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  and for all  $x \in X$ , we have  $\|f_n(x) - f(x)\| < \varepsilon$ ”. If we place the words “for all  $x \in X$ ” at the very beginning of the sentence, we get pointwise convergence.

Uniform convergence implies pointwise convergence: If  $\|f - f_n\|_\infty \rightarrow 0$ , then for each  $x \in X$  we have  $\|f_n(x) - f(x)\| \rightarrow 0$  since  $\|f(x) - f_n(x)\| \leq \|f - f_n\|_\infty$ .

**Example 3.42.** Let  $f_n : (0, 1) \rightarrow \mathbb{R}$  be  $f_n(x) = x^n$ . Then  $f_n$  converges pointwisely to 0 (cf. Exp. 4.10). But  $\sup_{x \in (0,1)} |x^n - 0| = 1$  does not converge to 0. So  $f_n$  does not converge uniformly to 0.

**Remark 3.43.** The uniform convergence of sequences in  $l^\infty(X, V)$  is induced by the  $l^\infty$ -norm, and hence is induced by the metric  $d(f, g) = \|f - g\|_\infty$ . However, this formula cannot be extended to a metric on  $V^X$ , since for arbitrary  $f, g \in V^X$ ,  $\|f - g\|_\infty$  is possibly  $+\infty$ .

In fact, it is true that the uniform convergence of sequences in  $V^X$  is induced by a metric, see Pb. 3.6. When  $X$  is countable, we have seen in Pb. 2.3 that the pointwise convergence in  $V^X$  is also given by a metric.  $\square$

**Theorem 3.44.** Let  $X$  be a set, and let  $V$  be a Banach space (over  $\mathbb{F}$ ). Then  $l^\infty(X, V)$  is a Banach space (over  $\mathbb{F}$ ).

*Proof.* Let  $(f_n)$  be a Cauchy sequence in  $l^\infty(X, V)$ . Then for every  $\varepsilon > 0$  there is  $N \in \mathbb{Z}_+$  such that for all  $m, n \geq N$  we have that  $\sup_{x \in X} \|f_n(x) - f_m(x)\| < \varepsilon$ , and hence  $\|f_n(x) - f_m(x)\| < \varepsilon$  for each  $x \in X$ . This shows that for each  $x \in X$ ,  $(f_n(x))$  is a Cauchy sequence in  $V$ , which converges to some element  $f(x) \in V$  because  $V$  is complete.

We come back to the statement that for each  $\varepsilon > 0$ , there exists  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  and all  $x$ ,

$$\|f_n(x) - f_m(x)\| < \varepsilon$$

for every  $m \geq N$ . Let  $m \rightarrow \infty$ . Then by the continuity of subtraction and taking norm (cf. Prop. 3.37.), we obtain  $\|f_n(x) - f(x)\| \leq \varepsilon$  for all  $n \geq N$  and  $x \in X$ . In other words,  $\|f_n - f\|_\infty \leq \varepsilon$  for all  $n \geq N$ . In particular,  $\|f\|_\infty \leq \|f_N\|_\infty + \|f_N - f\|_\infty < +\infty$  by (3.9). This proves  $f \in l^\infty(X, V)$  and  $f_n \rightrightarrows f$ .  $\square$

Mathematicians used to believe that “if a sequence of continuous functions  $f_n : [0, 1] \rightarrow \mathbb{R}$  converges pointwisely to a function  $f : [0, 1] \rightarrow \mathbb{R}$ , then  $f$  is continuous”. Cauchy, one of the main figures in 19th century working on putting analysis on a rigorous ground, has given a problematic proof of this wrong statement. Counterexamples were later found in the study of Fourier series: Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a function with period  $2\pi$  such that  $f(x) = x$  when  $-\pi < x < \pi$ , and  $f(x) = 0$  when  $x = \pm\pi$ . Then the Fourier series of this noncontinuous function  $f$  converges pointwisely to  $f$ , yet the partial sums of this series are clearly continuous functions. Later, it was realized that uniform convergence is needed to show the continuity of the limit function. (See Thm. 3.47.) This was the first time the importance of uniform convergence was realized.

The following discussions about (resp. sequentially compact) metric spaces also apply to general (resp. compact) topological spaces. The reader can come back and check the proofs for these more general spaces after studying them in the future.

**Definition 3.45.** Let  $X, Y$  be metric spaces (resp. topological spaces). Then  $C(X, Y)$  denotes the set of continuous functions from  $X$  to  $Y$ .

**Lemma 3.46.** Let  $X$  be a metric space (resp. a topological space), and let  $V$  be a normed vector space. Then  $C(X, V)$  is a linear subspace of  $V^X$ . If  $X$  is sequentially compact (resp. compact), then  $C(X, V)$  is a linear subspace of  $l^\infty(X, V)$ .

*Proof.* Using Prop. 3.37, one checks easily that  $C(X, V)$  is a linear subspace of  $V^X$ . For any  $f \in C(X, V)$ , the absolute value function  $|f| : x \in X \mapsto \|f(x)\|$  is continuous. Thus, assuming that  $X$  is sequentially compact, then by Lem. 3.2,  $|f|$  is bounded on  $X$ . This proves that  $\|f\|_\infty < +\infty$ . Thus  $C(X, V)$  is a subset (and hence a linear subspace) of  $l^\infty(X, V)$ .  $\square$

**Theorem 3.47.** Let  $X$  be a metric space (resp. a topological space), and let  $V$  be a normed vector space. Then  $C(X, V) \cap l^\infty(X, V)$  is a closed linear subspace of  $l^\infty(X, V)$ . In particular, if  $X$  is sequentially compact (resp. compact), then  $C(X, V)$  is a closed linear subspace of  $l^\infty(X, V)$ .

*Proof.* Choose a sequence  $(f_n)$  in  $C(X, V) \cap l^\infty(X, V)$  converging in  $l^\infty(X, V)$  to  $f$ . Namely,  $f_n \rightrightarrows f$ . We want to prove that  $f$  is continuous. We check that  $f$  satisfies Def. 2.38-(2'). (One can also use Def. 2.38-(1). The proofs using these two definitions are not substantially different.)

Fix  $p \in X$ . Choose any  $\varepsilon > 0$ . Since  $f_n \rightrightarrows f$ , there exists  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$  and we have  $\|f - f_n\|_\infty < \varepsilon$ . Since  $f_N$  is continuous, there exists  $r > 0$  such that for each  $x \in B_X(p, r)$  we have  $\|f_N(x) - f_N(p)\| < \varepsilon$ . Thus, for each  $x \in B_X(p, r)$  we have

$$\|f(x) - f(p)\| \leq \|f(x) - f_N(x)\| + \|f_N(x) - f_N(p)\| + \|f_N(p) - f(p)\| < 3\varepsilon$$

This finishes the proof.  $\square$

**Convention 3.48.** Unless otherwise stated, if  $X$  is sequentially compact metric space (or more generally, a compact topological space to be defined latter), and if  $V$  is a normed vector space, the norm on  $C(X, V)$  is chosen to be the  $l^\infty$ -norm.

**Corollary 3.49.** Let  $X$  be a metric space (resp. a topological space), and let  $V$  be a Banach space. Then  $C(X, V) \cap l^\infty(X, V)$  is a Banach space under the  $l^\infty$ -norm. In particular, if  $X$  is sequentially compact (resp. compact), then  $C(X, V)$  is a Banach space.

*Proof.* This follows immediately from Prop. 3.27, Thm. 3.47, and the fact that  $l^\infty(X, V)$  is complete (Thm. 3.44).  $\square$

### 3.5 Problems and supplementary material

**Problem 3.1.** Let  $(x_n)$  be a sequence in a metric space  $X$ . Let  $x \in X$ . Prove that the following are equivalent.

- (1)  $x$  is a cluster point of  $(x_n)$ , i.e., the limit of a convergent subsequence of  $(x_n)$ .
- (2) For each  $\varepsilon > 0$  and each  $N \in \mathbb{Z}_+$ , there exists  $n \geq N$  such that  $d(x_n, x) < \varepsilon$ .

(Note: in a general topological space, these two statements are not equivalent.)

**Remark 3.50.** Condition (2) is often abbreviated to “for each  $\varepsilon > 0$ , the sequence  $(x_n)$  is frequently in  $B(x, \varepsilon)$ ”. In general, we say “ $(x_n)$  **frequently** satisfies P” if for each  $N \in \mathbb{Z}_+$  there is  $n \geq N$  such that  $x_n$  satisfies P. We say that “ $(x_n)$  **eventually** satisfies P” if there exists  $N \in \mathbb{Z}_+$  such that for every  $n \geq N$ ,  $x_n$  satisfies P.

Thus “ $(x_n)$  eventually satisfies P” means the same as “all but finitely many  $x_n$  satisfies P”. Its negation is “ $(x_n)$  frequently satisfies  $\neg P$ ”.  $\square$

**Remark 3.51.** Condition (2) of Pb. 3.1 is sometimes easier to use than (1). For example, compared to the original definition of cluster points, it is much easier to find an explicit negation of (2) by using the rule suggested in Rem. 2.17: There exist  $\varepsilon > 0$  and  $N \in \mathbb{Z}_+$  such that  $d(x_n, x) \geq \varepsilon$  for all  $n \geq N$ . (Or simply: there exists  $\varepsilon > 0$  such that  $x_n$  is eventually not in  $B(x, \varepsilon)$ .)

**Problem 3.2.** Use Pb. 3.1-(2) to prove that if  $(x_n)$  is a sequence in  $\overline{\mathbb{R}}$ , then  $\limsup_{n \rightarrow \infty} x_n$  is a cluster point of  $(x_n)$ .

**Remark 3.52.** You will notice that your proof of Pb. 3.2 is slightly simpler than the proof we gave for Thm. 3.11. This is because our construction of subsequence as in (3.3) has been incorporated into your proof of (2) $\Rightarrow$ (1) in Pb. 3.1.

**Problem 3.3.** Let  $f : X \rightarrow Y$  be a continuous map of metric spaces. Assume that  $f$  is bijective and  $X$  is sequentially compact. Prove that  $f$  is a homeomorphism using the following hint.

*Hint.* You need to prove that if  $(y_n)$  is a sequence in  $Y$  converging to  $y \in Y$ , then  $x_n = f^{-1}(y_n)$  converges to  $x = f^{-1}(y)$ . Prove that  $(x_n)$  has only one cluster point, and hence converges to some point  $x' \in X$  (why?). Then prove  $x' = x$ . (In the future, we will use the language of open sets and closed sets to prove this result again. Do not use this language in your solution.)  $\square$

**Theorem 3.53 (Tychonoff theorem, countable version).** *Let  $(X_n)_{n \in \mathbb{Z}_+}$  be a sequence of sequentially compact metric spaces. Then the product space  $S = \prod_{n \in \mathbb{Z}_+} X_n$  is sequentially compact under the metric defined as in Pb. 2.3.*

The method of choosing subsequence in the following proof is the reknowned **diagonal method**.

*Proof.* Let  $(x_m)_{m \in \mathbb{Z}_+}$  be a sequence in  $S$ . Since  $(x_m(1))_{m \in \mathbb{Z}_+}$  is a sequence in the sequentially compact space  $X_1$ ,  $(x_m)_{m \in \mathbb{Z}_+}$  has a subsequence  $x_{1,1}, x_{1,2}, x_{1,3} \dots$  whose value at  $n = 1$  converges in  $X_1$ . Since  $X_2$  is sequentially compact, we can choose a subsequence  $x_{2,1}, x_{2,2}, x_{2,3}, \dots$  of the previous subsequence such that its values at  $n = 2$  converge in  $X_2$ . Then pick a subsequence from the previous one whose values at 3 converge in  $X_3$ .

By repeating this process, we get an  $\infty \times \infty$  matrix  $(x_{i,j})_{i,j \in \mathbb{Z}_+}$ :

$$\begin{array}{cccc} x_{1,1} & x_{1,2} & x_{1,3} & \cdots \\ x_{2,1} & x_{2,2} & x_{2,3} & \cdots \\ x_{3,1} & x_{3,2} & x_{3,3} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{array} \tag{3.10}$$

such that the following hold:

- The 1-st line is a subsequence of the original sequence  $(x_m)_{m \in \mathbb{Z}_+}$ .
- The  $(i + 1)$ -th line is a subsequence of the  $i$ -th line.
- For each  $n$ ,  $\lim_{j \rightarrow \infty} x_{n,j}(n)$  converges in  $X_n$ .

Then the diagonal line  $(x_{i,i})_{i \in \mathbb{Z}_+}$  is a subsequence of the original sequence  $(x_m)_{m \in \mathbb{Z}_+}$ . Moreover, for each  $n$ ,  $(x_{i,i})_{i \geq n}$  is a subsequence of the  $n$ -th line, whose value at  $n$  therefore converges in  $X_n$ . Thus  $\lim_{i \rightarrow \infty} x_{i,i}(n)$  converges in  $X_n$ . Thus, by Pb. 2.3,  $(x_{i,i})_{i \in \mathbb{Z}_+}$  converges under any metric inducing the product topology.  $\square$

**Problem 3.4.** Let  $X$  be a sequentially compact metric space. Let  $A \subset X$  be a metric subspace. Consider the statements:

- (1)  $A$  is sequentially compact.

(2)  $A$  is a closed subset of  $X$ .

Prove that (1) $\Rightarrow$ (2). Prove that if  $X$  is sequentially compact, then (2) $\Rightarrow$ (1).

The above problem implies immediately:

**Theorem 3.54 (Heine-Borel theorem).** *Let  $A$  be a subset of  $\mathbb{R}^N$ . Then  $A$  is sequentially compact iff  $A$  is a bounded closed subset of  $\mathbb{R}^N$ .*

*Proof.* Suppose that  $A$  is sequentially compact. Then  $A$  is bounded under the Euclidean metric by Prop. 3.7. By Pb. 3.4,  $A$  is a closed subset of  $\mathbb{R}^N$ .

Conversely, assume that  $A$  is a bounded and closed subset of  $\mathbb{R}^N$ . Then  $A \subset B$  where  $B$  is the product of  $N$  pieces of closed intervals in  $\mathbb{R}$ . Then  $B$  is sequentially compact by Bolzano-Weierstrass. Since  $A$  is closed in  $\mathbb{R}^N$ , it is not hard to check that  $A$  is closed in  $B$ .<sup>8</sup> Thus  $A$  is sequentially compact by Pb. 3.4.  $\square$

**Example 3.55.** Choose any  $p \in \mathbb{R}^N$  and  $0 \leq R < +\infty$ . Then  $\overline{B}_{\mathbb{R}^N}(p, R)$  is a bounded closed subset of  $\mathbb{R}^N$  (Exp. 3.30), and hence is sequentially compact by Heine-Borel.

**Remark 3.56.** Think about the question: Equip  $\mathbb{R}^{\mathbb{Z}_+}$  with metric

$$d(x, y) = \sup_{n \in \mathbb{Z}_+} \frac{\min\{|x(n), y(n)|, 1\}}{n}$$

What are the sequentially compact subsets of  $\mathbb{R}^{\mathbb{Z}_+}$ ? (Namely, think about how to generalize Heine-Borel theorem to  $\mathbb{R}^{\mathbb{Z}_+}$ .)

**Problem 3.5.** Do Exercise 3.40.

**Problem 3.6.** Let  $V$  be a normed vector space. For every  $f, g \in V^X$  define

$$d(f, g) = \min\{1, \|f - g\|_\infty\} \quad (3.11)$$

1. Show that  $d$  defines a metric on  $V^X$ .
2. Show for every sequence  $(f_n)$  in  $V^X$  and every  $g \in V^X$ , we have  $f_n \rightarrow g$  under the metric  $d$  iff  $f_n \rightrightarrows g$ .

**Definition 3.57.** Let  $X$  be a set, and let  $V$  be a normed vector space. A metric on  $V^X$  is called a **uniform convergence metric** if it is topologically equivalent to (3.11). Thus, by Def. 2.61, a uniform convergence metric is one such that a sequence  $(f_n)$  in  $V^X$  converges to  $f$  under this metric iff  $f_n \rightrightarrows f$ .

---

<sup>8</sup>If  $Z$  is a metric space, if  $X \subset Y \subset Z$ , and if  $X$  is closed in  $Z$ , then it is easy to check that  $X$  is closed in  $Y$ .

**Problem 3.7.** Let  $X, Y$  be metric spaces, and assume that  $Y$  is sequentially compact. Let  $V$  be a normed vector space. Choose  $f \in C(X \times Y, V)$ , i.e.,  $f : X \times Y \rightarrow V$  is continuous. For each  $x \in X$ , let

$$f_x : Y \rightarrow V \quad y \mapsto f(x, y)$$

Namely  $f_x(y) = f(x, y)$ . It is easy to check that  $f_x \in C(Y, V)$ . Define a new function

$$\Phi(f) : X \rightarrow C(Y, V) \quad x \mapsto f_x \quad (3.12)$$

Recall that  $C(Y, V)$  is equipped with the  $l^\infty$ -norm.

1. Prove that  $\Phi(f)$  is continuous. In other words, prove that if  $(x_n)$  is a sequence in  $X$  converging to  $x \in X$ , then  $f_{x_n} \rightrightarrows f_x$  on  $Y$ , i.e.

$$\lim_{n \rightarrow \infty} \|f_{x_n} - f_x\|_{l^\infty(Y, V)} = 0$$

- ★ 2. Give an example of  $f \in C(X \times Y, \mathbb{R})$  where  $Y$  is not sequentially compact,  $(x_n)$  converges to  $x$  in  $X$ , and  $f_{x_n}$  does not converge uniformly to  $f_x$ . (Note: you may consider  $X = Y = \mathbb{R}$ .)

*Hint.* In part 1, to prove that  $\Phi(f)$  is continuous, one can prove the equivalent fact that for every fixed  $x \in X$  the following is true:

- For every  $\varepsilon > 0$  there exists  $\delta > 0$  such that for all  $p \in B_X(x, \delta)$ , we have  $\sup_{y \in Y} \|f(p, y) - f(x, y)\| < \varepsilon$ .

(Cf. Def. 2.38.) Prove this by contradiction and by using the sequential compactness of  $Y$  appropriately. □

**Remark 3.58.** Let  $X = \mathbb{Z}_+ \cup \{\infty\}$ , equipped with the metric

$$d(m, n) = |m^{-1} - n^{-1}|$$

In other words, the metric on  $X$  is  $\tau^* d_{\mathbb{R}}$  where  $d_{\mathbb{R}}$  is the Euclidean metric on  $\mathbb{R}$ , and  $\tau : X \rightarrow \mathbb{R}, n \mapsto n^{-1}$ . It is not hard to show that  $X$  is sequentially compact: either prove it directly, or apply Heine-Borel to  $\tau(X)$ .

Let  $Y$  be a metric space. Let  $(y_n)_{n \in \mathbb{Z}_+}$  be a sequence in  $Y$ , and let  $y_\infty \in Y$ . It is not hard to see that the following two statements are equivalent:

- (1) The function  $F : X \rightarrow Y, n \mapsto y_n$  is continuous.
- (2) The sequence  $(y_n)_{n \in \mathbb{Z}_+}$  converges to  $y_\infty$ .

The following problem is a generalization of this equivalence. □

★ **Problem 3.8.** Let  $V$  be a normed vector space. Let  $Y$  be a metric space. Let  $X = \mathbb{Z}_+ \cup \{\infty\}$  with metric defined as in Rem. 3.58. Let  $(f_n)_{n \in \mathbb{Z}_+}$  be a sequence in  $C(Y, V)$ . Let  $f_\infty \in V^Y$ . Prove that the following are equivalent:

(1) The following function is continuous:

$$F : X \times Y \rightarrow V \quad (n, y) \mapsto f_n(y) \quad (3.13)$$

In particular, by restricting  $F$  to  $\infty \times Y$ , we see that  $f_\infty \in C(Y, V)$ .

(2)  $(f_n)_{n \in \mathbb{Z}_+}$  converges pointwisely to  $f_\infty$ . Moreover,  $(f_n)_{n \in \mathbb{Z}_+}$  is **pointwisely equicontinuous**, which means the following:

- For every  $y \in Y$  and every  $\varepsilon > 0$ , there exists  $\delta > 0$  such that for all  $p \in B_Y(y, \delta)$  we have

$$\sup_{n \in \mathbb{Z}_+} \|f_n(p) - f_n(y)\| < \varepsilon$$

*Note.* In part (1), the only nontrivial thing to prove is that  $F$  is continuous at  $(\infty, y)$  for every  $y \in Y$ .

**Remark 3.59.** There is a concise way to define pointwise equicontinuity: a sequence  $(f_n)_{n \in \mathbb{Z}_+}$  in  $V^Y$  is pointwisely equicontinuous iff the function

$$Y \mapsto V^{\mathbb{Z}_+} \quad y \mapsto (f_1(y), f_2(y), \dots) \quad (3.14)$$

is continuous, where  $V^{\mathbb{Z}_+}$  is equipped with any uniform convergence metric (cf. Def. 3.57).

★ **Remark 3.60.** In Pb. 3.8, there is a quick and tricky way to conclude (1) $\Rightarrow$ (2): Use Pb. 3.7 and the sequential compactness of  $X$ . (Do not use this method in your solution. Prove (1) $\Rightarrow$ (2) directly; it is a good exercise and is not difficult.)

★ **Remark 3.61.** Pb. 3.7 and 3.8, together with Thm. 3.47, imply the following fact (can you see why?):

- Let  $Y$  be a sequentially compact metric space. Let  $V$  be a normed vector space. Let  $(f_n)_{n \in \mathbb{Z}_+}$  be a pointwisely equicontinuous sequence of functions  $Y \rightarrow V$  converging pointwisely to some  $f : Y \rightarrow V$ . Then  $f_n \rightrightarrows f$  on  $Y$ .

You can also try to give a straightforward proof of this fact without using Pb. 3.7 and 3.8.

## 4 Series

In this chapter, we assume that vector spaces are over  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$  unless otherwise stated.

### 4.1 Definitions and basic properties

**Definition 4.1.** Let  $V$  be a Banach space (over  $\mathbb{F}$ ). A **series** in  $V$  is an expression of the form

$$\sum_{i=1}^{\infty} v_i \quad (4.1)$$

where  $(v_i)_{i \in \mathbb{Z}_+}$  is a sequence in  $V$ . If  $s \in V$ , we say that the series (4.1) **converges to  $s$**  if

$$s = \lim_{n \rightarrow \infty} \sum_{i=1}^n v_i$$

namely,  $s_n \rightarrow s$  where  $s_n$  is the **partial sum**  $s_n = \sum_{i=1}^n v_i$ . In this case, we write

$$s = \sum_{i=1}^{\infty} v_i$$

**Remark 4.2.** Since  $V$  is complete, the series (4.1) converges iff the sequence of partial sum  $(s_n)$  is a Cauchy sequence: for every  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that for all  $n > m \geq N$  we have  $\|s_n - s_m\| < \varepsilon$ , i.e.,

$$\left\| \sum_{i=m+1}^n v_i \right\| < \varepsilon \quad (4.2)$$

**Proposition 4.3.** Suppose that  $\sum_{i=1}^{\infty} v_i$  is a convergent series in a Banach space  $V$ . Then  $\lim_{n \rightarrow \infty} v_n = 0$ .

*Proof.* Let  $s_n = v_1 + \cdots + v_n$ , which converges to  $s \in V$ . Then  $\lim_{n \rightarrow \infty} s_{n+1} = s$ . So  $v_n = s_{n+1} - s_n \rightarrow s - s = 0$  since subtraction in continuous (Prop. 3.37).  $\square$

Thus, for example,  $\sum_{n=1}^{\infty} (-1)^n$  diverges in the Banach space  $\mathbb{R}$  since  $\lim_{n \rightarrow \infty} (-1)^n$  does not converge to 0.

**Definition 4.4.** Consider a **series** in  $\overline{\mathbb{R}}_{\geq 0}$ :

$$\sum_{i=1}^{\infty} a_i \quad (4.3)$$

namely, each  $a_i$  is in  $\overline{\mathbb{R}}_{\geq 0}$ . Note that the partial sum  $s_n = \sum_{i=1}^n a_i$  is increasing. We say that  $\lim_{n \rightarrow \infty} s_n$  (which exists in  $\overline{\mathbb{R}}_{\geq 0}$  and equals  $\sup\{s_n : n \in \mathbb{Z}_+\}$ , cf. Rem. 2.71) is the value of the series (4.3) and write

$$\sum_{i=1}^{\infty} a_i = \lim_{n \rightarrow \infty} s_n$$

**Definition 4.5.** We say that a series  $\sum_{i=1}^{\infty} a_i$  in  $\mathbb{R}_{\geq 0}$  **converges** if it converges in  $\mathbb{R}$  (but not just converges in  $\overline{\mathbb{R}}_{\geq 0}$ , which is always true). Clearly,  $\sum_{i=1}^{\infty} a_i$  converges iff

$$\sum_{i=1}^{\infty} a_i < +\infty$$

More generally, we say that a series  $\sum_{i=1}^{\infty} v_i$  in a Banach space  $V$  **converges absolutely**, if

$$\sum_{i=1}^{\infty} \|v_i\| < +\infty$$

**Remark 4.6.** By the Cauchy condition of convergence,  $\sum_{i=1}^{\infty} v_i$  converges absolutely iff for every  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that for all  $n > m \geq N$  we have

$$\sum_{i=m+1}^n \|v_i\| < \varepsilon \quad (4.4)$$

By comparing (4.4) with (4.2) and using the subadditivity of the norm (recall Def. 3.33), we immediately see:

**Proposition 4.7.** Let  $\sum_{i=1}^{\infty} v_i$  be a series in a Banach space. The following are true.

1. If  $\sum_{i=1}^{\infty} v_i$  converges absolutely, then it converges.
2. For each  $i$  we choose  $a_i \in \mathbb{R}_{\geq 0}$  satisfying  $\|v_i\| \leq a_i$ . Suppose that  $\sum_{i=1}^{\infty} a_i < +\infty$ . Then  $\sum_{i=1}^{\infty} v_i$  converges absolutely.

*Proof.* Part 1 has been explained above. In part 2, we have  $\sum \|v_i\| \leq \sum a_i < +\infty$ . So  $\sum v_i$  converges absolutely.  $\square$

**Exercise 4.8.** Suppose that  $\sum_{i=1}^{\infty} u_i$  and  $\sum_{i=1}^{\infty} v_i$  are convergent (resp. absolutely convergent) series in a Banach space  $V$ . Let  $\lambda \in \mathbb{F}$ . Show that the LHS of the following equations converges (resp. converges absolutely) in  $V$ , and that the following equations hold:

$$\begin{aligned} \sum_{i=1}^{\infty} (u_i + v_i) &= \sum_{i=1}^{\infty} u_i + \sum_{i=1}^{\infty} v_i \\ \sum_{i=1}^{\infty} \lambda v_i &= \lambda \cdot \sum_{i=1}^{\infty} v_i \end{aligned}$$

**Remark 4.9.** We have seen that absolute convergence implies convergence. In fact, at least when  $V = \mathbb{F}^N$ , absolute convergence is in many ways more natural than convergence. For example, we will learn that if a series  $\sum_i v_i$  in  $\mathbb{F}^N$  converges absolutely, then the value of  $\sum_i v_i$  is invariant under rearrangement of the series: for every bijection  $\varphi : \mathbb{Z}_+ \rightarrow \mathbb{Z}_+$  we have  $\sum_i v_i = \sum_i v_{\varphi(i)}$ . In the next semester, we shall learn Lebesgue integral theory and, more generally, measure theory. When applying measure theory to infinite sums over the countable set  $\mathbb{Z}_+$ , many good results (e.g. dominated convergence theorem, Fubini theorem) hold only for absolute convergence series, but not for arbitrary convergent series in general. In fact, there is no analog of convergent (but not absolutely convergent) series in measure theory at all!

When  $V$  is not necessarily finite-dimensional, the situation is subtler: there is a version of convergence which lies between the usual convergence and absolute convergence, and which coincides with absolute convergence when  $V = \mathbb{F}^N$ . This version of convergence is defined using nets instead of sequences. Moreover, many good properties (as mentioned above) hold for this convergence, and these properties can be proved in a very conceptual way (rather than using brute-force computation). We will learn this convergence in the next chapter.  $\square$

## 4.2 Basic examples

Let us study the **geometric series**  $\sum_{n=0}^{\infty} z^n$  where  $z \in \mathbb{C}$ . We first note the useful formula: for each  $z, w \in \mathbb{C}$  and  $n \in \mathbb{N}$ ,

$$(z + w)^n = \sum_{k=0}^n \binom{n}{k} z^k w^{n-k} \quad (4.5)$$

In particular,

$$(1 + z)^n = 1 + nz + \frac{n(n-1)}{2} z^2 + \frac{n(n-1)(n-2)}{6} z^3 + \cdots + nz^{n-1} + z^n \quad (4.6)$$

**Example 4.10.** Assume  $z \in \mathbb{C}$  and  $|z| < 1$ . Then  $\lim_{n \rightarrow \infty} z^n = 0$ .

*Proof.* If  $z = 0$  then it is obvious. Assume that  $0 < |z| < 1$ . Choose  $\delta > 0$  such that  $|z| = 1/(1 + \delta)$ . By (4.6),  $(1 + \delta)^n \geq 1 + n\delta$ . So

$$0 \leq |z^n| \leq (1 + n\delta)^{-1}$$

Since  $\lim_{n \rightarrow \infty} (1 + n\delta)^{-1} = 0$ , we have  $|z^n| \rightarrow 0$  by squeeze theorem. Hence  $z^n \rightarrow 0$ .  $\square$

**Example 4.11.** Let  $z \in \mathbb{C}$ . If  $|z| < 1$ , then  $\sum_{n=0}^{\infty} z^n$  converges absolutely, and

$$\sum_{n=0}^{\infty} z^n = \frac{1}{1 - z} \quad (4.7)$$

where  $0^0$  is understood as 1. If  $|z| \geq 1$ , then  $\sum_{n=0}^{\infty} z^n$  diverges in  $\mathbb{C}$ .

*Proof.* The partial sum  $s_n = 1 + z + z^2 + \cdots + z^n$  equals  $(1 - z^{n+1})/(1 - z)$  when  $z \neq 1$ . Therefore, when  $|z| < 1$ ,  $s_n \rightarrow 1/(1 - z)$ . When  $|z| \geq 1$ , we have  $|z^n| \geq 1$  and hence  $z^n \not\rightarrow 0$ . So  $\sum_{n=0}^{\infty} z^n$  diverges by Prop. 4.3.  $\square$

**Example 4.12.** The harmonic series  $\sum_{n=1}^{\infty} \frac{1}{n}$  diverges (in  $\mathbb{R}$ ).

*Proof.* We want to show that the Cauchy condition (cf. Rem. 4.2) does not hold. Thus, we want to prove that there exists  $\varepsilon > 0$  such that for every  $N \in \mathbb{Z}_+$  there exist  $n > m \geq N$  such that  $|(m+1)^{-1} + (m+2)^{-1} + \cdots + n^{-1}| \geq \varepsilon$ .

To see this, for each  $N$  we choose  $m = 2^N$  and  $n = 2^{N+1}$ . Then  $n > m > N$ , and

$$\begin{aligned} \left| \sum_{i=m+1}^n i^{-1} \right| &= \left| \frac{1}{2^N+1} + \frac{1}{2^N+2} + \cdots + \frac{1}{2^N+2^N} \right| \\ &\geq \underbrace{\left| \frac{1}{2^{N+1}} + \frac{1}{2^{N+1}} + \cdots + \frac{1}{2^{N+1}} \right|}_{2^N \text{ terms}} = \varepsilon \end{aligned}$$

where  $\varepsilon = \frac{1}{2}$ .  $\square$

**Exercise 4.13.** Choose any  $p \in \mathbb{Z}$ . Prove that  $\sum_{n=1}^{\infty} n^{-p}$  converges iff  $p \geq 2$ .

*Hint.* Use Prop. 4.7 and Exp. 4.12 to reduce the problem to the case  $p = 2$ . Prove this case by proving  $\sum_{n=1}^{\infty} 1/n(n+1) = 1 < +\infty$ .  $\square$

**Definition 4.14.** Let  $V$  be a Banach space, let  $X$  be a set, and let  $(f_n)$  be a sequence in  $l^\infty(X, V)$ , and let  $g \in l^\infty(X, V)$ . We say that the series of functions  $\sum_{i=1}^{\infty} f_i$  **converges uniformly to  $g$**  (on  $X$ ) if it converges to  $g$  as a series in the Banach space  $l^\infty(X, V)$  and under the  $l^\infty$ -norm. Equivalently, this means that the partial sum function  $s_n = f_1 + \cdots + f_n$  converges uniformly to  $g$  as  $n \rightarrow \infty$ .

**Example 4.15.** The series of functions  $\sum_{n=1}^{\infty} \frac{\sin |nz^3|}{n^2}$  converges uniformly on  $\mathbb{C}$  to a continuous function  $g : \mathbb{C} \rightarrow \mathbb{R}$  which is uniformly bounded (i.e.  $\sup_{z \in \mathbb{C}} |g(z)| < +\infty$ ).

*Proof.* Let  $f_n(z) = \sin |nz^3|/n^2$ . Then each  $f_n$  is in  $\mathfrak{X} = C(\mathbb{C}, \mathbb{R}) \cap l^\infty(\mathbb{C}, \mathbb{R})$  where  $\mathfrak{X}$  is a real Banach space under the  $l^\infty$ -norm by Cor. 3.49. Note that  $\|f_n\|_\infty \leq n^{-2}$ . By Exe. 4.13,  $\sum_{n=1}^{\infty} n^{-2} < +\infty$ . Therefore, by Prop. 4.7, the series  $\sum_n f_n$  converges in  $\mathfrak{X}$ , i.e., it converges uniformly to an element  $g \in \mathfrak{X}$ . (In particular,  $\sum_n f_n(z) = g(z)$  for all  $z \in \mathbb{C}$ .)  $\square$

### 4.3 Root test and ratio test; power series; construction of $e^z$

Root test and ratio test are useful criteria for proving the convergence or divergence of series, especially power series. In addition, the method of power series provides a unified and elegant proof for many useful formulas about limit (see Prop. 4.23 and Exp. 4.24). We begin our discussion with the following easy observation:

**Remark 4.16.** Let  $(x_n)$  be a sequence in  $\overline{\mathbb{R}}$ , and let  $A \in \overline{\mathbb{R}}$ . The following are true.

1. If  $\limsup_{n \rightarrow \infty} x_n < A$ , then  $x_n < A$  is eventually true.
2. If  $\limsup_{n \rightarrow \infty} x_n > A$ , then  $x_n > A$  is frequently true.

By taking negative, we obtain similar statements for  $\liminf$ .

*Proof.* Recall that  $\limsup x_n = \inf_{n \in \mathbb{Z}_+} \alpha_n$  where  $\alpha_n = \sup\{x_n, x_{n+1}, \dots\}$ .

Assume that  $\inf_{n \in \mathbb{Z}_+} \alpha_n < A$ . Then  $A$  is not a lower bound of  $\{\alpha_n : n \in \mathbb{Z}_+\}$ . Thus, there exists  $N \in \mathbb{Z}_+$  such that  $\alpha_N < A$ . Then  $x_n < A$  for all  $n \geq N$ .

Assume that  $\inf_{n \in \mathbb{Z}_+} \alpha_n > A$ . Then for each  $N \in \mathbb{Z}_+$  we have  $\alpha_N > A$ . So  $A$  is not an upper bound of  $\{x_n, x_{n+1}, \dots\}$ . So there is  $n \geq N$  such that  $x_n > A$ .  $\square$

We will heavily use  $\sqrt[n]{x}$  (where  $x \geq 0$  and  $n \in \mathbb{Z}_+$ ) in the following discussions.  $\sqrt[n]{x}$  will be rigorously constructed in Exp. 7.93, whose proof does not rely on the results of this section.

**Proposition 4.17 (Root test).** Let  $\sum_{n=1}^{\infty} v_n$  be a series in a Banach space  $V$ . Let  $\beta = \limsup_{n \rightarrow \infty} \sqrt[n]{\|v_n\|}$ . Then:

1. If  $\beta < 1$ , then  $\sum v_n$  converges absolutely, and hence converges in  $V$ .
2. If  $\beta > 1$ , then  $\sum v_n$  diverges in  $V$ .

*Proof.* Suppose  $\beta < 1$ . Then we can choose  $\gamma$  such that  $\beta < \gamma < 1$ . So  $\limsup \sqrt[n]{\|v_n\|} < \gamma$ . By Rem. 3.8, there exists  $N \in \mathbb{Z}_+$  such that for all  $n \geq N$ , we have  $\sqrt[n]{\|v_n\|} < \gamma$ , and hence  $\|v_n\| < \gamma^n$ . Since  $\sum_{n=0}^{\infty} \gamma^n = (1 - \gamma)^{-1} < +\infty$  (Exp. 4.11), the series  $\sum_{n=N}^{\infty} v_n$  converges absolutely by Prop. 4.7. So the original series converges absolutely.

Assume that  $\beta > 1$ . Then by Rem. 4.16, for each  $N$  there is  $n \geq N$  such that  $\sqrt[n]{\|v_n\|} > 1$  and hence  $\|v_n - 0\| > 1$ . So  $v_n \not\rightarrow 0$ . So  $\sum v_n$  diverges by Prop. 4.3.  $\square$

**Example 4.18.** Let  $V = \mathbb{R}$  and  $v_n = 1/n$  resp.  $v_n = 1/n^2$ . Then  $\beta = 1$ , and  $\sum v_n$  diverges resp. converges absolutely due to Exe. 4.13. So Root test gives no information on the convergence of series when  $\beta = 1$ . The same can be said about ratio test.

**Proposition 4.19 (Ratio test).** Let  $\sum_{n=1}^{\infty} v_n$  be a series in a Banach space  $V$  such that  $v_n \neq 0$  for all  $n$ . Let  $\alpha = \liminf_{n \rightarrow \infty} \frac{\|v_{n+1}\|}{\|v_n\|}$  and  $\beta = \limsup_{n \rightarrow \infty} \frac{\|v_{n+1}\|}{\|v_n\|}$ . Then:

1. If  $\beta < 1$ , then  $\sum v_n$  converges absolutely, and hence converges in  $V$ .
2. If  $\alpha > 1$ , then  $\sum v_n$  diverges in  $V$ .

*Proof.* Suppose  $\beta < 1$ . Choose  $\gamma$  such that  $\beta < \gamma < 1$ . Then by Rem. 4.16, there is  $N$  such that for all  $n \geq N$  we have  $\|v_{n+1}\|/\|v_n\| < \gamma$ . So  $\|v_n\| < \gamma^{n-N} \|v_N\|$ . So  $\sum_{n \geq N} \|v_n\| \leq \|v_N\| \cdot \sum_{n \geq N} \gamma^{n-N} = \|v_N\| \cdot (1 - \gamma)^{-1} < +\infty$ . So  $\sum v_n$  converges absolutely.

Suppose  $\alpha > 1$ . Then by Rem. 4.16, there is  $N$  such that for all  $n \geq N$  we have  $\|v_{n+1}\|/\|v_n\| > 1$ . So  $\|v_n\| \geq \|v_N\| > 0$  for all  $n \geq N$ . So  $v_n \not\rightarrow 0$  and hence  $\sum v_n$  diverges, as in the proof of root test.  $\square$

**Definition 4.20.** A **power series** in a complex Banach space  $V$  is an expression of the form  $\sum_{n=0}^{\infty} v_n z^n$  where the **coefficients**  $v_0, v_1, v_2, \dots$  are elements of  $V$ , and  $z$  is a **complex variable**, i.e., a symbol which can take arbitrary values in  $\mathbb{C}$ . If the power series  $\sum v_n z^n$  converges at  $z_0 \in \mathbb{C}$ , we often let  $\sum v_n z_0^n$  denote this limit.

**Proposition 4.21.** Let  $\sum v_n z^n$  be a power series in a complex Banach space  $V$ . Then there is a unique  $0 \leq R \leq +\infty$  satisfying the following properties:

- (a) If  $z \in \mathbb{C}$  and  $|z| < R$ , then  $\sum v_n z^n$  converges absolutely in  $V$ .
- (b) If  $z \in \mathbb{C}$  and  $|z| > R$ , then  $\sum v_n z^n$  diverges in  $V$ .

Such  $R$  is called the **radius of convergence** of  $\sum v_n z^n$ . Moreover, we have

$$R = \frac{1}{\limsup_{n \rightarrow \infty} \sqrt[n]{\|v_n\|}} = \liminf_{n \rightarrow \infty} \frac{1}{\sqrt[n]{\|v_n\|}} \quad (4.8)$$

*Proof.* Clearly, there are at most one  $R$  satisfying (a) and (b). Let us define  $R$  using (4.8) (note that the second and the third terms of (4.8) are clearly equal), and prove that  $R$  satisfies (a) and (b). Let

$$\beta(z) = \limsup_{n \rightarrow \infty} \sqrt[n]{\|v_n z^n\|}$$

Then  $\beta(z) = |z|/R$ . So (a) and (b) follow immediately from root test.  $\square$

**Remark 4.22.** Note that if one can find  $0 \leq r \leq R$  such that  $\sum v_n z^n$  converges whenever  $|z| < r$ , then  $r \leq R$  where  $R$  is the radius of convergence: otherwise, the series diverges for any positive  $z$  satisfying  $R < z < r$ , impossible.

It follows that if  $\sum v_n z^n$  converges for all  $|z| < r$ , then  $\sum v_n z^n$  converges *absolutely* for all  $|z| < r$ .  $\square$

Prop. 4.21 provides a useful method for computing limits of a positive sequence:

**Proposition 4.23.** *Let  $(\lambda_n)$  be a sequence in  $\mathbb{R}_{>0}$ . Then*

$$\liminf_{n \rightarrow \infty} \frac{\lambda_{n+1}}{\lambda_n} \leq \liminf_{n \rightarrow \infty} \sqrt[n]{\lambda_n} \leq \limsup_{n \rightarrow \infty} \sqrt[n]{\lambda_n} \leq \limsup_{n \rightarrow \infty} \frac{\lambda_{n+1}}{\lambda_n} \quad (4.9)$$

In particular, (by Cor. 3.18) we have

$$\lim_{n \rightarrow \infty} \sqrt[n]{\lambda_n} = \lim_{n \rightarrow \infty} \frac{\lambda_{n+1}}{\lambda_n} \quad (4.10)$$

provided that the limit on the RHS of (4.10) exists in  $\overline{\mathbb{R}}$ .

The four numbers in (4.9) can be completely different. See [Rud-P, Exp. 3.35].

*Proof.* Let  $R$  be the radius of convergence of  $\sum \lambda_n z^n$ . Then  $R = 1/\limsup \sqrt[n]{\lambda_n}$  by (4.10). Thus, by Prop. 4.21, if  $|z| > R$  then  $\sum \lambda_n z^n$  diverges, and hence  $\limsup |\lambda_{n+1} z^{n+1}|/|\lambda_n z^n| \geq 1$  by ratio test. Therefore,

$$|z| > \frac{1}{\limsup \sqrt[n]{\lambda_n}} \implies |z| \cdot \limsup \frac{\lambda_{n+1}}{\lambda_n} \geq 1$$

This proves

$$\limsup \sqrt[n]{\lambda_n} \leq \limsup \frac{\lambda_{n+1}}{\lambda_n}$$

Replacing  $\lambda_n$  by  $\lambda_n^{-1}$ , we get

$$\frac{1}{\liminf \sqrt[n]{\lambda_n}} = \limsup \sqrt[n]{\lambda_n^{-1}} \leq \limsup \frac{\lambda_n}{\lambda_{n+1}} = \frac{1}{\liminf \frac{\lambda_{n+1}}{\lambda_n}}$$

This proves (4.9). □

**Example 4.24.** Let  $a \in \mathbb{R}_{>0}$  and  $p \in \mathbb{Z}$ . The following formulas follow immediately from Prop. 4.23 (especially, from (4.10)):

$$\lim_{n \rightarrow \infty} \sqrt[n]{a} = 1 \quad (4.11a)$$

$$\lim_{n \rightarrow \infty} \sqrt[n]{n!} = +\infty \quad (4.11b)$$

$$\lim_{n \rightarrow \infty} \sqrt[n]{n^p} = 1 \quad (4.11c)$$

Note that (4.11c) follows from

$$\lim_{n \rightarrow \infty} \left( \frac{n}{n+1} \right)^p = 1 \quad (4.11d)$$

(This is clearly true when  $p = \pm 1$ , and hence is true for any  $p$  by induction.) By (4.11c), the radius of convergence of  $\sum_n n^p z^n$  is 1. Therefore, by Prop. 4.21,  $\sum n^p A^{-n}$  converges absolutely when  $A > 1$ . Thus, by Prop. 4.3,

$$\lim_{n \rightarrow \infty} \frac{n^p}{A^n} = 0 \quad (\text{if } A > 1) \quad (4.11e)$$

This means that “polynomials grow slower than exponentials”.

The same conclusions hold for arbitrary  $p \in \mathbb{R}$  once we know how to define  $x^p$  and prove the continuity of  $x \in \mathbb{R}_{>0} \mapsto x^p$ . (See Sec. 7.7.)  $\square$

★ **Exercise 4.25.** Prove (4.11a) directly. Then use (4.11a) to give a direct proof of Prop. 4.23. Do not use root test, ratio test, or any results about power series.

**Definition 4.26.** By (4.11b), the power series

$$\exp(z) \equiv e^z = \sum_{n=0}^{\infty} \frac{z^n}{n!}$$

has radius of convergence  $+\infty$ , and hence converges absolutely on  $\mathbb{C}$ . (In particular,  $\lim_{n \rightarrow \infty} z^n/n! = 0$  for all  $z \in \mathbb{C}$ .) This gives a function  $\exp : \mathbb{C} \rightarrow \mathbb{C}$ , called the **exponential function**.

Part (a) of Prop. 4.21 can be strengthened in the following way.

**Theorem 4.27.** Let  $\sum v_n z^n$  be a power series with coefficients in a complex Banach space  $V$ . Let  $R$  be its radius of convergence, and assume that  $0 < R \leq +\infty$ . For each  $z \in B_{\mathbb{C}}(0, R)$ , let  $f(z)$  denote the value of this series at  $z$  (which is an element of  $V$ ). Then  $f : B_{\mathbb{C}}(0, R) \rightarrow V$  is continuous. Moreover, for each  $0 < \rho < R$ , the series of functions  $\sum v_n z^n$  converges uniformly on  $\overline{B}_{\mathbb{C}}(0, \rho)$  to  $f$ .

Note that by calling  $\sum v_n z^n$  a series of functions, we understand each term  $v_n z^n$  as a function  $\mathbb{C} \rightarrow V$ .

*Proof.* For each  $0 < \rho < R$ , let  $X_\rho = \overline{B}_{\mathbb{C}}(0, \rho)$ . Then  $X_\rho$  is clearly a bounded closed subset of  $\mathbb{C}$ , and hence is sequentially compact by Heine-Borel Thm. 3.54. Let  $g_n = v_n z^n$ , which is a continuous function  $X_\rho \rightarrow V$ . We view  $g_n$  as an element of the Banach space (cf. Cor. 3.49)  $C(X_\rho, V)$ . Then  $\|g_n\|_\infty = \rho^n \|v_n\|$ . Thus

$$\limsup_{n \rightarrow \infty} \sqrt[n]{\|g_n\|_\infty} = \limsup_{n \rightarrow \infty} \rho \sqrt[n]{\|v_n\|} = \rho/R < 1$$

Therefore, by root test, the series  $\sum g_n$  converges in the Banach space  $C(X_\rho, V)$  to some  $f_\rho \in C(X_\rho, V)$ .

We have proved that for each  $0 < \rho < R$ , the series of functions  $\sum v_n z^n$  converges uniformly on  $X_\rho$  to a continuous function  $f_\rho$ . Let  $f : B_{\mathbb{C}}(0, R) \rightarrow V$  whose value at each  $z$  is the value of the original series at  $z$ . Thus, if  $|z| \leq \rho$ , then

$f_\rho(z) = f(z)$ . Namely,  $f|_{X_\rho} = f_\rho$ . This shows that  $\sum v_n z^n$  converges uniformly on  $X_\rho$  to  $f$ . It also shows that  $f|_{B_{\mathbb{C}}(0,\rho)}$  is continuous (because  $f_\rho$  is continuous). Therefore, since  $B_{\mathbb{C}}(0, R)$  is covered by all open disks  $B_{\mathbb{C}}(0, \rho)$  (where  $0 < \rho < R$ ), we conclude from Lem. 2.41 that  $f$  is continuous on  $B_{\mathbb{C}}(0, R)$ .  $\square$

**Example 4.28.** By Thm. 4.27, the exponential function  $\exp : \mathbb{C} \rightarrow \mathbb{C}$  is continuous; moreover,  $\sum_{n=0}^{\infty} z^n/n!$  converges uniformly to  $e^z$  on  $\overline{B_{\mathbb{C}}}(0, R)$  for every  $0 < R < +\infty$ , and hence on every bounded subset of  $\mathbb{C}$ .

## 5 Nets and discrete integrals

### 5.1 Introduction: why do we need nets?

Nets were introduced by Moore and Smith in 1922 as a generalization of sequences. The most well-known motivation for introducing nets is that sequences are not enough for the study of non-metrizable topological spaces (i.e. topological spaces whose topologies are not induced by metrics). Here are two examples:

- In a general topological space, the definition of continuous maps using sequential convergence (as in Def. 2.38-(1)) is weaker than the definition using interior points and open sets (as in Def. 2.38-(2')), see also Rem. 4.23). Therefore, the dynamic intuition of sequences is not equivalent to the static intuition of open sets.
- Some important topological spaces are compact (i.e. every open cover has a finite subcover) but not sequentially compact.  $[0, 1]^I$  (where  $I$  is uncountable), equipped with the “product topology” (i.e. “pointwise convergence topology”), is such an example.

As we shall see, nets provide a remedy for these issues: For a general topological space, the definition of continuity using net convergence is equivalent to that using open sets; compactness is equivalent to “net-compactness”, where the latter means that every net has a convergent subnet. Thus, by generalizing sequences to nets, the dynamic intuition and the static and geometric intuition are unified again.

Nevertheless, the most common topological spaces appearing in analysis are metrizable. This raises the question: Why should we care about nets, given that our primary interest is in metrizable topological spaces? Here is my answer: Even though we are mainly interested in metrizable spaces, we can still find nets helpful in the following aspects.

First of all, many convergence processes cannot be described by sequential convergence, but can be described by net convergence. For example, the following limits can be formulated and understood in the language of net convergence:

- (1) The limit of a function  $\lim_{x \rightarrow x_0} f(x)$  where  $f : X \rightarrow Y$  is a map of metric spaces and  $x_0 \in X$ .
- (2) The limit  $\lim_{m, n \rightarrow \infty} a_{m, n}$  where  $(a_{m, n})_{m, n \in \mathbb{Z}_+}$  is a **double sequence** in a metric space  $X$ . Note that this is not the same as (but is more natural than) the **iterated limit**  $\lim_{n \rightarrow \infty} \lim_{m \rightarrow \infty} a_{m, n}$ . Moreover, the limit  $\lim_{m, n \rightarrow \infty} a_{m, n}$  is the key to understanding the problem of commutativity of iterated integrals:

$$\lim_{n \rightarrow \infty} \lim_{m \rightarrow \infty} a_{m, n} \stackrel{?}{=} \lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} a_{m, n}$$

- (3) The Riemann integral  $\int_a^b f(x)dx$ . This is the limit of the Riemann sum  $\lim \sum f(\xi_i)(a_i - a_{i-1})$  as the partition of the interval  $[a, b]$  is getting finer and finer.

Moreover, as for (3), we shall see that the net version of Cor. 3.18 provides a quick and conceptual proof of the following fact: If the upper and lower Darboux integrals are equal, then the Riemann integral exists and are equal to the two Darboux integrals. Indeed, the upper and lower Darboux integrals are respectively the  $\limsup$  and  $\liminf$  of a net in  $\mathbb{R}$ .

Second, nets provide a conceptual solution to many problems about **double series**. Let  $(a_{m,n})_{m,n \in \mathbb{Z}_+}$  be a double sequence in  $\mathbb{R}$ . Think about the following questions, which arise naturally when one is trying to prove  $e^z e^w = e^{z+w}$ .

- (a) When is it true that  $\sum_{n=1}^{\infty} \sum_{m=1}^{\infty} a_{m,n} = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} a_{m,n}$  ?
- (b) Since  $\text{card}(\mathbb{Z}_+ \times \mathbb{Z}_+) = \text{card}(\mathbb{Z}_+)$ , why not use an ordinary series to study a double series? So let us **parametrize**  $\mathbb{Z}_+ \times \mathbb{Z}_+$  by  $\mathbb{Z}_+$ : choose a bijection  $\varphi : \mathbb{Z}_+ \rightarrow \mathbb{Z}_+ \times \mathbb{Z}_+$ . When is it true that  $\sum_{k=1}^{\infty} a_{\varphi(k)} = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} a_{m,n}$  ?
- (c) Choose another parametrization (i.e. bijection)  $\psi : \mathbb{Z}_+ \rightarrow \mathbb{Z}_+ \times \mathbb{Z}_+$ . When is it true that  $\sum_{k=1}^{\infty} a_{\varphi(k)} = \sum_{k=1}^{\infty} a_{\psi(k)}$  ?
- (d) More generally, let  $X$  be a countably infinite set, and let  $f : X \rightarrow \mathbb{R}$ . Intuitively, we can take an infinite sum  $\sum_{x \in X} f(x)$ . How to define it rigorously? One may think about choosing a parametrization, i.e., a bijection  $\varphi : \mathbb{Z}_+ \rightarrow X$ . Then one defines the infinite sum by  $\sum_{k=1}^{\infty} f(\varphi(k))$ . Is this definition independent of the choice of parametrization?
- (e) As a special case of (d), when is a series invariant under **rearrangement**? Namely, choose a bijection  $\varphi : \mathbb{Z}_+ \rightarrow \mathbb{Z}_+$ , and choose a sequence  $(a_n)$  in  $\mathbb{R}$ , when is it true that  $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} a_{\varphi(n)}$  ?

Modern differential geometry (whose “intrinsic” spirit stems from Gauss’s Theorema Egregium) teaches us that in order to answer these questions, one should first define the infinite sum  $\sum_{x \in X} f(x)$  in a parametrization-independent way. (The reason we call a bijection  $\varphi : \mathbb{Z}_+ \rightarrow X$  a parametrization is that we want the readers to compare it with the parametrizations of curves, surfaces, and more generally manifolds.) We will call this sum a **discrete integral**. Then, one tries to answer when this definition agrees with those that depend on parametrizations

(such as the sums in (a)-(e) above). These goals can be achieved with the help of nets.

## 5.2 Nets

### 5.2.1 Directed sets and nets

**Definition 5.1.** A relation  $\leq$  on a set  $I$  is called a **preorder** if for all  $\alpha, \beta, \gamma \in I$ , the following are satisfied:

- (Reflexivity)  $\alpha \leq \alpha$ .
- (Transitivity) If  $\alpha \leq \beta$  and  $\beta \leq \gamma$  then  $\alpha \leq \gamma$ .

The pair  $(I, \leq)$  (or simply  $I$ ) is called a **preordered set**.

Therefore, a partial order is a preorder satisfying antisymmetry:  $(\alpha \leq \beta) \wedge (\beta \leq \alpha) \Rightarrow (\alpha = \beta)$ .

**Definition 5.2.** A preordered set  $(I, \leq)$  is called a **directed set** if

$$\forall \alpha, \beta \in I \quad \exists \gamma \in I \quad \text{such that } \alpha \leq \gamma, \beta \leq \gamma \quad (5.1)$$

If  $I$  is a directed set and  $X$  is a set, then a function  $x : I \rightarrow X$  is called a **net** with directed set/index set  $I$ . We often write  $x(\alpha)$  as  $x_\alpha$  if  $\alpha \in I$ , and write  $x$  as  $(x_\alpha)_{\alpha \in I}$ .

**Example 5.3.**  $(\mathbb{Z}_+, \leq)$  is a directed set. A net with index set  $\mathbb{Z}_+$  in a set  $X$  is precisely a sequence in  $X$ .

**Definition 5.4.** Suppose that  $(I, \leq_I)$  and  $(J, \leq_J)$  are preordered set (resp. directed set), then the **product**  $(I \times J, \leq)$  is a preordered set (resp. directed set) if for every  $\alpha, \alpha' \in I, \beta, \beta' \in J$  we define

$$(\alpha, \beta) \leq (\alpha', \beta') \iff \alpha \leq_I \alpha' \text{ and } \beta \leq_J \beta' \quad (5.2)$$

Unless otherwise stated, the preorder on  $I \times J$  is assumed to be defined by (5.2).

**Example 5.5.**  $\mathbb{Z}_+ \times \mathbb{Z}_+$  (or similarly,  $\mathbb{N} \times \mathbb{N}$ ) is naturally a directed set whose preorder is defined by (5.2). A net  $(x_{m,n})_{(m,n) \in \mathbb{Z}_+ \times \mathbb{Z}_+}$  with index set  $\mathbb{Z}_+ \times \mathbb{Z}_+$  is called a **double sequence** and is written as  $(x_{m,n})_{m,n \in \mathbb{Z}_+}$  or simply  $(x_{m,n})$ . (We will even write it as  $(x_{mn})$  when no confusion arises.)

More generally, we call  $(x_{\alpha,\beta})_{(\alpha,\beta) \in I \times J} = (x_{\alpha,\beta})_{\alpha \in I, \beta \in J}$  a **double net** if its index set is  $I \times J$  for some directed sets  $I, J$ .  $\square$

**Example 5.6.** If  $X$  is a set, then  $(2^X, \subset)$  and  $(\text{fin}(2^X), \subset)$  are directed sets where

$$\text{fin}(2^X) = \{A \subset X : A \text{ is a finite set}\} \quad (5.3)$$

We will use nets with index set  $\text{fin}(2^X)$  to study infinite sums.

**Example 5.7.** Let  $X$  be a metric space and  $x \in X$ . Then  $X_x = (X, \leq)$  is a directed set if for each  $p_1, p_2 \in X$  we define

$$p_1 \leq p_2 \text{ in } X_x \iff d(p_1, x) \geq d(p_2, x) \quad (5.4)$$

(Namely, a larger element of  $X_x$  is one closer to  $x$ .) Nets with this directed set can be used to study the limits of functions (cf. Rem. 7.108). Note that  $X_x$  is our first example of directed set which is not a poset! ( $d(p_1, x) = d(p_2, x)$  does not imply  $p_1 = p_2$ .)

### 5.2.2 Limits of nets

If  $I$  is an preordered set and  $\beta \in I$ , we write

$$I_{\geq \beta} = \{\alpha \in I : \alpha \geq \beta\} \quad (5.5)$$

**Definition 5.8.** Let  $P$  be a property about elements of a set  $X$ , i.e.,  $P$  is a function  $X \rightarrow \{\text{true}, \text{false}\}$ . Let  $(x_\alpha)_{\alpha \in I}$  be a net in  $X$ .

We say that  $x_\alpha$  **eventually** satisfies  $P$  (equivalently, we say that  $x_\alpha$  satisfies  $P$  for **sufficiently large**  $\alpha$ ) if:

- There exists  $\beta \in I$  such that for every  $\alpha \in I_{\geq \beta}$ , the element  $x_\alpha$  satisfies  $P$ .

“Sufficiently large” is also called “**large enough**”.

We say that  $x_\alpha$  **frequently** satisfies  $P$  if:

- For every  $\beta \in I$  there exists  $\alpha \in I_{\geq \beta}$  such that  $x_\alpha$  satisfies  $P$ .

□

**Remark 5.9.** Note that unlike sequences, for a general net, “ $x_\alpha$  eventually satisfies  $P$ ” does not imply “all but finitely many  $x_\alpha$  satisfy  $P$ ” because the complement of  $I_{\geq \beta}$  is not necessarily a finite set.

**Remark 5.10.** Let  $P$  and  $Q$  be two properties about elements of  $X$ . Then

$$\neg(x_\alpha \text{ eventually satisfies } P) = (x_\alpha \text{ frequently satisfies } \neg P) \quad (5.6a)$$

By the crucial condition (5.1) for directed sets, we have

$$\begin{aligned} (x_\alpha \text{ eventually satisfies } P) \wedge (x_\alpha \text{ eventually satisfies } Q) \\ \Downarrow \\ x_\alpha \text{ eventually satisfies } P \wedge Q \end{aligned} \quad (5.6b)$$

By taking contraposition and replacing  $P, Q$  by  $\neg P, \neg Q$ , we have

$$\begin{aligned} x_\alpha \text{ frequently satisfies } P \vee Q \\ \Downarrow \\ (x_\alpha \text{ frequently satisfies } P) \vee (x_\alpha \text{ frequently satisfies } Q) \end{aligned} \quad (5.6c)$$

**Definition 5.11.** Let  $(x_\alpha)_{\alpha \in I}$  be a net in a metric space  $X$ . Let  $x \in X$ . We say that  $(x_\alpha)$  **converges to**  $x$  and write

$$\lim_{\alpha \in I} x_\alpha \equiv \lim_{\alpha} x_\alpha = x$$

or simply  $x_\alpha \rightarrow x$  if the following statement holds:

- For every  $\varepsilon > 0$ ,  $x_\alpha$  is eventually in  $B_X(x, \varepsilon)$ .

Clearly,  $x_\alpha \rightarrow x$  iff  $d(x_\alpha, x) \rightarrow 0$ .

**Definition 5.12.** Let  $(x_{m,n})_{m,n \in \mathbb{Z}_+}$  be a double sequence in a metric space. Then we write

$$\lim_{(m,n) \in \mathbb{Z}_+ \times \mathbb{Z}_+} x_{m,n} \equiv \lim_{m,n \rightarrow \infty} x_{m,n} \quad (5.7)$$

and call it the **(double) limit** of  $(x_{m,n})$ .

**Remark 5.13.** Let us spell out the meaning of  $\lim_{m,n \rightarrow \infty} x_{m,n} = x$ : For each  $\varepsilon > 0$  there exists  $M, N \in \mathbb{Z}_+$  such that  $d(x_{m,n}, x) < \varepsilon$  for all  $m \geq M$  and  $n \geq N$ . Clearly, this is equivalent to the statement:

- For each  $\varepsilon > 0$  there exists  $N \in \mathbb{Z}_+$  such that  $d(x_{m,n}, x) < \varepsilon$  for all  $m, n \geq N$ .

Therefore, if  $(x_n)$  is a sequence in  $X$ , then

$$(x_n) \text{ is a Cauchy sequence} \iff \lim_{m,n \rightarrow \infty} d(x_m, x_n) = 0 \quad (5.8)$$

Thus, the Cauchy-ness of sequences can be studied in terms of double limits, and hence in terms of nets.

**Proposition 5.14.** Let  $(x_\alpha)_{\alpha \in I}$  be a net in a metric space  $X$  converging to  $x, y$ . Then  $x = y$ .

*Proof.* Suppose that  $x \neq y$ . Then there are  $r, \rho > 0$  such that  $B(x, r) \cap B(y, \rho) = \emptyset$ , say  $r = \rho = d(x, y)/2$ . Since  $x_\alpha \rightarrow x$ , the point  $x_\alpha$  is eventually in  $B(x, r)$ . Since  $x_\alpha \rightarrow y$ , the point  $x_\alpha$  is eventually in  $B(y, \rho)$ . Therefore, by the logic (5.6b),  $x_\alpha$  is eventually in  $B(x, r) \cap B(y, \rho)$ , impossible.  $\square$

**Theorem 5.15.** Let  $f : X \rightarrow Y$  be map of metric spaces continuous at  $x \in X$ . Let  $(x_\alpha)_{\alpha \in I}$  be a net in  $X$  converging to  $x$ . Then  $\lim_{\alpha} f(x_\alpha) = f(x)$ .

*Proof.* Choose any  $\varepsilon > 0$ . By Def. 2.38-(2) and the continuity of  $f$  at  $x$ , there exists  $\delta > 0$  such that for all  $p \in B(x, \delta)$  we have  $f(p) \in B(f(x), \varepsilon)$ . Since  $x_\alpha \rightarrow x$ ,  $x_\alpha$  is eventually in  $B(x, \delta)$ . Therefore  $f(x_\alpha)$  is eventually in  $B(f(x), \varepsilon)$ .  $\square$

This theorem implies, for example, that if  $(v_\alpha)$  is a net in a complex normed vector space converging to  $v$ , and if  $(\lambda_\alpha)$  is a net in  $\mathbb{C}$  converging to  $\lambda$ , then  $\lambda_\alpha v_\alpha$  converges to  $\lambda v$  because the scalar multiplication map is continuous (Prop. 3.37).

**Exercise 5.16.** Prove the generalization of Rem. 2.71:

1. If  $(x_\alpha)_{\alpha \in I}, (y_\alpha)_{\alpha \in I}$  are nets in  $\overline{\mathbb{R}}$  converging to  $A, B \in \overline{\mathbb{R}}$ , and if  $x_\alpha \leq y_\alpha$  for all  $\alpha$ , then  $A \leq B$ .
2. **Squeeze theorem:** Suppose that  $(x_\alpha)_{\alpha \in I}, (y_\alpha)_{\alpha \in I}, (z_\alpha)_{\alpha \in I}$  are nets in  $\overline{\mathbb{R}}$ ,  $x_\alpha \leq y_\alpha \leq z_\alpha$  for all  $\alpha$ , and  $x_\alpha$  and  $z_\alpha$  both converge to  $A \in \overline{\mathbb{R}}$ . Then  $y_\alpha \rightarrow A$ .
3. If  $(x_\alpha)$  is an increasing resp. decreasing net in  $\overline{\mathbb{R}}$ , then  $\lim_\alpha x_\alpha$  exists in  $\overline{\mathbb{R}}$  and equals  $\sup_\alpha x_\alpha$  resp.  $\inf_\alpha x_\alpha$ .

### 5.2.3 Subnets (in the sense of Willard)

**Definition 5.17.** A subset  $E$  of a directed set  $I$  is called **cofinal** if:

$$\forall \alpha \in I \quad \exists \beta \in E \quad \text{such that } \alpha \leq \beta$$

By the transitivity in Def. 5.1 and property (5.1), we clearly have

$$\forall \alpha_1, \dots, \alpha_n \in I \quad \exists \beta \in E \quad \text{such that } \alpha_1 \leq \beta, \dots, \alpha_n \leq \beta$$

**Definition 5.18.** Let  $(x_\alpha)_{\alpha \in I}$  be a net in a set  $X$ . A **subnet** of  $(x_\alpha)_{\alpha \in I}$  is, by definition, of the form  $(x_{\alpha_s})_{s \in S}$  where  $S$  is a directed set, and

$$(\alpha_s)_{s \in S} : S \rightarrow I \quad s \mapsto \alpha_s$$

is an increasing function whose range  $\{\alpha_s : s \in S\}$  is cofinal in  $I$ .

**Remark 5.19.** There are several different definitions of subnets that are equivalent for proving the main results in point-set topology. Unfortunately, there is no common agreement on the standard definition of subnets. The definition we gave is due to Willard [Wil], and is also the one given in the famous textbook of Munkres [Mun]. Some famous analysis and topology textbooks (e.g. [Fol, Kel, RS]) use a weaker definition, which does not assume that the map  $S \rightarrow I$  is increasing.

**Example 5.20.** A subsequence is a subnet.

**Example 5.21.** Let  $(x_{m,n})_{m,n \in \mathbb{Z}_+}$  be a net with index set  $\mathbb{Z}_+ \times \mathbb{Z}_+$ . Then  $(x_{k,k})_{k \in \mathbb{Z}_+}$  and  $(x_{2k,k})_{k \in \mathbb{Z}_+}$  are subnets.  $(x_{k,1})_{k \in \mathbb{Z}_+}$  is not a subnet, because the cofinal condition is not satisfied. More generally, it is not hard to show that for every function  $\varphi, \psi : \mathbb{Z}_+ \rightarrow \mathbb{Z}_+$ ,  $(x_{\varphi(k), \psi(k)})_{k \in \mathbb{Z}_+}$  is a subnet iff  $\varphi, \psi$  are increasing and  $\lim_{k \rightarrow \infty} \varphi(k) = \lim_{k \rightarrow \infty} \psi(k) = +\infty$ .

**Exercise 5.22.** Prove the following facts:

- The cofinal subset of a cofinal subset of a directed set  $I$  is a cofinal subset of  $I$ .
- The subnet of a subnet of a net  $(x_\alpha)$  is a subnet of  $(x_\alpha)$ .

Note that in your proof you need to use the transitivity in Def. 5.1.

The biggest difference between subnets and subsequences is that the index set of a subnet is not necessarily a subset of the index set of the original net. Indeed, subnets are defined in this way mainly because we want to have a net version of Pb. 3.1 in any topological space. (This will be achieved in Pb. 7.2.) Let us see an elementary example of subnet whose index set is larger than that of the original net. Its importance is justified by the proofs of Exp. 5.28 and Prop. 5.34.

**Example 5.23.** Let  $J$  be a directed set. Then every net  $(x_\alpha)_{\alpha \in I}$  has subnet  $(x_\alpha)_{(\alpha, \beta) \in I \times J}$ . The corresponding increasing map of directed sets is the projection  $I \times J \rightarrow I$  onto the first component.

To appreciate the importance of cofinality (as well as transitivity), we prove the following generalization of Prop. 2.36. This result has a wide range of surprising applications that are unavailable when one only considers sequences. (We will see them soon in this chapter. For instance, this result explains why the values of absolutely convergent series are invariant under rearrangement.) So I call this result a theorem, even though its proof is simple.

**Theorem 5.24.** *Let  $(x_\alpha)_{\alpha \in I}$  be a net in a metric space (or more generally, a topological space)  $X$  converging to  $x \in X$ . Then every subnet  $(x_{\alpha_s})_{s \in S}$  converges to  $x$ .*

The following proof for metric spaces can be generalized straightforwardly to topological spaces. The readers can come back and check the details after learning topological spaces.

*Proof.* Choose any  $\varepsilon > 0$ . Since  $x_\alpha \rightarrow x$ , there exists  $\beta \in I$  such that for all  $\alpha \geq \beta$  we have  $d(x_\alpha, x) < \varepsilon$ . By the cofinality, there exists  $t \in S$  such that  $\alpha_t \geq \beta$ . Thus, since  $s \in S \mapsto \alpha_s \in I$  is increasing, for every  $s \geq t$ , we have  $\alpha_s \geq \alpha_t \geq \beta$  and hence  $\alpha_s \geq \beta$  by the transitivity in Def. 5.1. So  $d(x_{\alpha_s}, x) < \varepsilon$  for all  $s \geq t$ . This finishes the proof.  $\square$

This proposition does not hold if one does not assume cofinality in the definition of subnets:

**Example 5.25.** Let  $(x_n)$  be a sequence in  $\mathbb{R}$  converging to  $x \in \mathbb{R}$ . Since  $(x_n)$  is a Cauchy sequence, we know that  $\lim_{m, n \rightarrow \infty} x_m - x_n = 0$ . We have seen in Exp. 5.21 that  $(x_{2k} - x_k)_{k \in \mathbb{Z}_+}$  is a subnet of  $(x_{m, n})$ . Therefore,  $\lim_{k \rightarrow \infty} x_{2k} - x_k = 0$ . But

$(x_k - x_1)_{k \in \mathbb{Z}_+}$  is not a subnet since the cofinal condition is not satisfied. And if  $x \neq x_1$ , then  $\lim_k (x_k - x_1) = x - x_1 \neq 0$ , i.e.,

$$\lim_{k \rightarrow \infty} (x_k - x_1) \neq \lim_{m, n \rightarrow \infty} (x_m - x_n)$$

In Subsec. 2.3.2, we have seen two criteria for the divergence of sequence: a sequence diverges if it is unbounded, or if it has two subsequences converging to different points. By Thm. 5.24, the second criterion can be generalized to nets. However, the following example shows that the first criterion does not has its net version:

**Example 5.26.** A convergent net  $(x_\alpha)_{\alpha \in I}$  in a metric space  $X$  is not necessarily **bounded**. Namely, it is not necessarily true that  $\{x_\alpha : \alpha \in I\}$  is a bounded subset of  $X$ . Let  $f : \mathbb{R}_{>0} \rightarrow \mathbb{R}$  be  $f(x) = 1/x$ . Then  $f$  is net in  $\mathbb{R}$  with directed set  $(\mathbb{R}_{>0}, \leq)$ . This net is not bounded, although  $\lim f(x) = 0$ .

**Example 5.27.** The double sequence  $x_{m,n} = n/(m+n)$  in  $\mathbb{R}$  has subnets  $x_{n,n} = n/(n+n) = 1/2$  and  $x_{2n,n} = 1/3$ . Since these two subnets converge to different values, Thm. 5.24 implies that  $\lim_{m,n} x_{m,n}$  does not exist. However, the **iterated limits** exist and take different values:

$$\lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} \frac{n}{m+n} = 1 \quad \lim_{n \rightarrow \infty} \lim_{m \rightarrow \infty} \frac{n}{m+n} = 0$$

As we shall see, this gives another criterion for the divergence of double series: If the two iterated limits exist and are different, then the double series diverge.

Finally, we do an example of convergent double sequence:

**Example 5.28.** Let  $x_{m,n} = (m^{-2} - n^{-1}) \sin \frac{\pi(m + \sqrt{n})}{4}$ . Then  $\lim_{m,n \rightarrow \infty} x_{m,n} = 0$ .

*Proof.* The sequence  $(m^{-2})_{m \in \mathbb{Z}_+}$  converges to 0. By Exp. 5.23, the double sequence  $(m^{-2})_{m,n \in \mathbb{Z}_+}$  is its subnet, and hence converges to 0 by Thm. 5.24. Similarly, the double sequence  $(n^{-1})_{m,n \in \mathbb{Z}_+}$  converges to 0. Therefore,  $m^{-2} + n^{-1}$  converges to 0 due to Thm. 5.15 and the continuity of the addition map  $(x, y) \in \mathbb{R}' \rightarrow x + y \in \mathbb{R}$  (Prop. 2.45). Since  $0 \leq |x_{m,n}| \leq m^{-2} + n^{-1}$ , we conclude  $|x_{m,n}| \rightarrow 0$  (and hence  $x_{m,n} \rightarrow 0$ ) by squeeze theorem (Exe. 5.16).  $\square$
