Preface

In this volume I should like to give a rapid account of the fundamental ideas, methods, and principal results of a theory which is due almost exclusively to contemporary mathematicians. Personally, I have contributed very little to this theory; and if I have undertaken the present work, it is because I was encouraged to do so by my investigations into several neighboring subjects, among them orthogonal systems of functions, integral equations, and functional operations. Continued by several authors, these investigations have proved more or less fruitful for applications of the present theory; and, on the other hand, they have enabled me to present some parts of it from new points of view. Thus, for example, I was able to connect the study of the spectrum of quadratic forms in infinitely many variables with that of linear functional operations.

Our subject does not belong to the Theory of Functions in the strict sense. It should rather be regarded as marking a first stage in the still nascent Theory of Functions of Infinitely Many Variables, which may perhaps soon furnish the most powerful methods in all of Analysis. In any event, I believe that the subject and arrangement of the present volume accord well with the general plan of this Collection, in which M. Borel kindly offered to include it.

Finally, I wish to thank M. Fréchet and M. Marcel Riesz for the valuable advice they gave me during the correction of the proofs.

Kolozsvár, June 12, 1913.

FRÉDÉRIC RIESZ

Chapter I.

The Beginnings of the Theory

The Method of Undetermined Coefficients

1. The theory of equations with infinitely many unknowns is not of long standing. Indeed, scarcely any such theory existed before 1886, the year in which Poincaré demonstrated the legitimacy of the method of determinants of infinite order. General attention, moreover, was not really drawn to it until two memoirs by Hilbert appeared in 1906 as part of a series of memoirs on Fredholm's equation; from that time onward the theory developed rapidly, and the importance and unexpected character of the results obtained caused almost everything already known before then to be forgotten.

Yet theories have their beginnings: vague allusions, unfinished attempts, particular problems; and even when these beginnings matter little in the present state of science, it would be wrong to pass them over in silence.

2. The study of systems of equations with infinitely many unknowns arose from the method of undetermined coefficients. This method, used since the seventeenth century for integrating differential equations by series and for other problems, consists in principle in replacing the function sought by a series with unknown coefficients. The data of the problem will then make it possible to establish among these unknown coefficients, infinite in number, infinitely many relations; this is the system of equations with infinitely many unknowns.

For most problems treated in this way, however, the infinitude of the number of unknowns involved no difficulty at all and, it seems, no one even realized that a new idea was involved. This was because only recurrent systems arose, in which each equation by itself contained only finitely many unknowns, and one had to solve only finite systems, though infinitely many times.

Fourier and the Principle of Sections

3. While studying a special case of what is now called the Dirichlet problem, Fourier encountered, in his *Analytical Theory of Heat*, a system that was no longer recurrent. He proposed to determine a solution $v(x, y)$ of the partial differential equation

$$v_{xx} + v_{yy} = 0, \quad (1)$$

valid in the domain

$$x > 0, \quad -\frac{\pi}{2} < y < \frac{\pi}{2},$$

equal to 1 for $x = 0$, vanishing for $y = \pm\pi/2$ and for $x = \infty$.¹ Here is how he proceeds. First he sets

$$v(x, y) = F(x)f(y)$$

and seeks to satisfy equation (1) without regard to the boundary data. He thus finds the particular solution

$$v(x, y) = e^{-mx} \cos my, \quad (2)$$

where m denotes an arbitrary real number. On choosing m positive, integral, and odd, solution (2) satisfies the boundary conditions except the first. Fourier therefore sets

$$v(x, y) = \sum_{m=1}^{\infty} a_m e^{-(2m-1)x} \cos(2m-1)y;$$

it remains only to determine the coefficients a_m so that, for $x = 0$, the sum $v(x, y)$ of the series reduces to 1. This amounts, he says, to requiring

$$1 = \sum_{m=1}^{\infty} a_m \cos(2m-1)y. \quad (3)$$

To eliminate the variable y , he differentiates the equation term by term infinitely many times and puts $y = 0$; this gives

$$\begin{cases} 1 = \sum a_m, \\ 0 = \sum (2m-1)^2 a_m, \\ 0 = \sum (2m-1)^4 a_m, \\ \dots \end{cases} \quad (4)$$

¹Art. 166 and following.

a system of infinitely many linear equations in the infinitely many unknowns a_m .

4. To solve it, Fourier takes the first k equations, retains in them only the first k unknowns, and neglects all terms depending on the remaining unknowns. Denoting the unknowns of this reduced system by

$$a_1^{(k)}, a_2^{(k)}, \dots, a_k^{(k)},$$

one obtains, by an easy calculation,

$$a_1^{(k)} = \frac{9 \cdot 25 \cdots (2k-1)^2}{8 \cdot 24 \cdots (4k^2 - 4k)},$$

which, by a well-known formula of Wallis, gives

$$\lim_{k \rightarrow \infty} a_1^{(k)} = \frac{4}{\pi}.$$

Moreover, for $m < k$, the reduced system gives

$$\frac{a_{m+1}^{(k)}}{a_m^{(k)}} = \frac{2m-1}{2m+1} \frac{m-k}{m+k},$$

hence

$$\lim_{k \rightarrow \infty} \frac{a_{m+1}^{(k)}}{a_m^{(k)}} = -\frac{2m-1}{2m+1},$$

and, by induction,

$$\lim_{k \rightarrow \infty} a_m^{(k)} = (-1)^{m-1} \frac{4}{\pi(2m-1)}.^2$$

Finally, putting

$$a_m = \lim_{k \rightarrow \infty} a_m^{(k)},$$

we obtain

$$v(x, y) = \frac{4}{\pi} \sum_{m=1}^{\infty} (-1)^{m-1} \frac{e^{-(2m-1)x} \cos(2m-1)y}{2m-1}. \quad (5)$$

²We have just calculated this limiting value by a route different from Fourier's, whose calculation is somewhat more laborious. The essential principles of the argument are not thereby altered.

5. This result of Fourier is undoubtedly correct. Indeed, comparing series (5) and its derivatives of every order respectively with the series

$$\sum \frac{e^{-(2m-1)x_0}}{2m-1}, \quad \sum e^{-(2m-1)x_0}, \quad \sum (2m-1)e^{-(2m-1)x_0}, \quad \dots,$$

one concludes that they converge uniformly for $x \geq x_0 > 0$, that they tend uniformly to zero as x increases indefinitely, that $v(x, y)$ vanishes for $x > 0$, $y = \pm\pi/2$, and finally, since termwise differentiation is legitimate, that $v(x, y)$ satisfies equation (1). On the portion $x = 0$, $-\pi/2 < y < \pi/2$ of the boundary of the domain, series (5) converges to the limit 1, uniformly on every segment $(-\pi/2 + h, \pi/2 - h)$; moreover $v(x, y)$ tends to this value when, from within the domain, one approaches such a segment indefinitely. At the points $(0, \pi/2)$ and $(0, -\pi/2)$, where the prescribed values undergo abrupt changes, $v(x, y)$ remains indeterminate, the limiting bounds of indeterminacy being 0 and 1.

All these facts are connected with the following observation. Introducing the variables

$$r = e^{-x}, \quad \theta = y, \quad z = re^{i\theta},$$

which makes the half-disk

$$r < 1, \quad -\frac{\pi}{2} < \theta < \frac{\pi}{2}$$

correspond to the domain considered, the function $v(x, y)$ becomes the real part of one of the branches of the analytic function

$$f(z) = \frac{1}{2i} \log \frac{i-z}{i+z}.$$

This real part has a very simple geometric meaning: it is equal to half the angle whose sides join the point z to the points i and $-i$. All the stated consequences follow from this.

6. Fourier's result is therefore correct. But serious objections may be raised against his reasoning. Fourier was reasoning about an unknown series; he could not suspect the dangers that threatened him, and in that period confidence still prevailed. Since then, however, greater caution has been brought to every question involving infinity. Had Fourier shared our mistrust, would he have dared to take the path he followed?

Let us merely indicate the most perilous stage of his argument. He reduces his problem to that of determining a series of the form (3) which represents, throughout

the interval $(-\pi/2, \pi/2)$, the function constantly equal to 1. To calculate the a_m , he differentiates equation (3) infinitely many times and puts $y = 0$, thereby obtaining system (4). But from the second equation onward, the series occurring there diverge after the a_m have been replaced by the values $(-1)^{m-1}4/[\pi(2m-1)]$ that were found. Thus at first sight the values obtained for the a_m do not appear to satisfy system (4).

Fortunately, we now know how to interpret broad classes of divergent series by assigning them sums that retain certain principal properties of sums of convergent series. From this point of view, to justify Fourier's procedure one need only replace system (4) by

$$\begin{cases} 1 = \lim_{r \rightarrow 1-0} \sum a_m r^{2m-1}, \\ 0 = \lim_{r \rightarrow 1-0} \sum (2m-1)^2 a_m r^{2m-1}, \\ 0 = \lim_{r \rightarrow 1-0} \sum (2m-1)^4 a_m r^{2m-1}, \\ \dots \end{cases} \quad (6)$$

This interpretation of system (4) is entirely in accord with the problem being treated.³ Indeed, the values found for the a_m satisfy system (6), and this fact is connected with the holomorphy at $z = 1$ of the function $f(z)$ defined above.

7. Fourier also applies his method to a more general problem: to expand in a trigonometric series an odd function given by its Taylor series

$$f(x) = f'(0)x + \frac{f'''(0)}{3!}x^3 + \dots \quad .^4$$

Since the function is assumed odd, one must evidently find an expansion of the form

$$f(x) = \sum_{m=1}^{\infty} b_m \sin mx. \quad (7)$$

To determine the b_m , Fourier uses a procedure like the one just described: he differentiates both sides of (7) infinitely many times and sets $x = 0$; or rather,

³Other summation methods might also have been used; for example, the series in question

$$\sum \frac{(-1)^{m-1}}{(2m-1)^{2k+1}}$$

is summable by arithmetic means of order $2k$, and this procedure likewise gives the sum 0 for $k > 0$.

⁴Art. 207 and following.

what amounts to the same thing, he expands both sides in power series and compares coefficients of like powers. This procedure gives him an infinite system of equations in the unknowns b_m ; he takes the first k , retains only the first k unknowns, and solves the reduced system; he then passes to the limit, if one may call the extremely bold calculation he performs a passage to the limit. That calculation gives

$$b_m = (-1)^{m+1} \frac{2}{m\pi} \left[f(\pi) - \frac{1}{m^2} f''(\pi) + \frac{1}{m^4} f^{IV}(\pi) - \dots \right].$$

To deduce the final result, Fourier observes that the series

$$s(x) = f(x) - \frac{1}{m^2} f''(x) + \frac{1}{m^4} f^{IV}(x) - \dots$$

satisfies the differential equation

$$\frac{1}{m^2} s''(x) + s(x) = f(x).$$

The general integral of this equation is

$$\begin{aligned} s(x) = & C_1 \cos mx + C_2 \sin mx + m \sin mx \int_0^x f(t) \cos mt \, dt \\ & - m \cos mx \int_0^x f(t) \sin mt \, dt. \end{aligned}$$

Since $s(x)$, like $f(x)$, is odd, one has

$$C_1 = s(0) = 0;$$

and, on putting $x = \pi$, one obtains the well-known formula

$$b_m = \frac{2}{\pi} \int_0^\pi f(x) \sin mx \, dx. \quad (8)$$

8. Fourier's reasoning is not correct, and could be made so only under very restrictive conditions on the given function $f(x)$. On the other hand, since the theory of trigonometric series has subsequently been based on firmer foundations, we now know that the validity of formula (8) requires only very broad conditions. For the theory of trigonometric series, Fourier's argument is merely an interesting curiosity of purely historical value. For us, however, it contains something very

valuable: it implies an exceedingly fruitful principle from the standpoint of our equations. Here is that principle, which must of course still be made much more precise: to solve an infinite system of equations with infinitely many unknowns, restrict the system to its first k equations and neglect in them all unknowns except the first k . As k tends to infinity, the solutions of these systems tend to the solution of the proposed system.

This principle, whose legitimacy can be justified under broad hypotheses, will prove very fruitful for the theory before us. We shall call it the *principle of sections*.

9. We have just examined the principle of sections from the point of view of Fourier's use of it. Let us now consider the same principle starting from a classical theorem in the Theory of Functions. According to Weierstrass, given an infinite sequence of quantities a_i such that $|a_i| \rightarrow \infty$, there exists an entire function

$$\mathfrak{F}(z) = C_0 + C_1 z + C_2 z^2 + \dots$$

having the a_i as zeros and no others. The coefficients $C_0, C_1, C_2, \dots$ must satisfy the equations

$$C_0 + C_1 a_i + C_2 a_i^2 + \dots = 0 \quad (i = 1, 2, \dots).$$

For definiteness, suppose the a_i are distinct and nonzero. The principle of sections, applied to these equations, then leads to the successive products

$$\prod_{i=1}^n \left(1 - \frac{z}{a_i}\right) = C_0^{(n)} + C_1^{(n)} z + \dots + C_n^{(n)} z^n, \quad C_0^{(n)} = 1.$$

Indeed, each of these products corresponds to one of the reduced systems, so that this system is satisfied by $C_0^{(n)}, \dots, C_n^{(n)}$. But this procedure is known to converge only if the $|a_k|$ increase sufficiently rapidly. Thus our equations can always be solved, but the principle of sections applies only under very restrictive conditions.

Weierstrass's method consists in adjoining exponential factors to the products above so as to accelerate convergence. One may hope that this method will some day be generalized so as to perfect the principle of sections. Up to the present, this has not been attempted.

Fürstenau and Kötteritzsch

10. Although Fourier's *Analytical Theory* has always remained the source of numerous investigations, the portions just recalled have fallen almost entirely into

oblivion. For more than half a century, the authors who dealt with our subject were led to it independently of Fourier and without referring to one another. Only in a memoir by G. Piola do we find Fourier's investigations cited; that author applied the same principle of sections to a particular problem.⁵

The next two authors in historical order, E. Fürstenau and Th. Kötteritzsch, are of no importance for the development of the theory. Their works nevertheless contain methods in embryonic form which, rediscovered and made rigorous in recent years, have proved very fruitful for the theory under consideration.

11. Fürstenau considers the following problem:

Given the equation

$$c_0 + c_1x + \cdots + c_mx^m = 0 \quad (c_0 \neq 0), \quad (9)$$

*calculate the root having the least absolute value.*⁶ For this purpose he successively multiplies the equation by higher and higher powers of x , and replaces x^n by x_n ; this procedure leads him to the infinite system

$$\begin{cases} -c_0 = c_1x_1 + c_2x_2 + \cdots + c_mx_m, \\ 0 = c_0x_1 + c_1x_2 + \cdots + c_{m-1}x_m + c_mx_{m+1}, \\ 0 = c_0x_2 + \cdots + c_{m-2}x_m + c_{m-1}x_{m+1} + c_mx_{m+2}, \\ \dots \end{cases}$$

To derive an expression for x_1 , he applies the principle of sections. He obtains

$$x_1 = -c_0 \lim_{n \rightarrow \infty} \frac{\Delta_{n-1}}{\Delta_n}, \quad (10)$$

where Δ_n is the determinant formed from the coefficients of $x_1, \dots, x_n$ in the first n equations.

When there is only one root of least absolute value and this root is simple, it is given by expression (10). Fürstenau's memoir proves this result with complete rigor, but by a rather laborious calculation. According to an observation of

⁵Piola, *Sulla teoria delle funzioni discontinue*, *Memorie della Società Italiana delle Scienze*, vol. XX, pp. 573–639. We cite this memoir from the reference supplied by G. Loria, *Supplemento ai Rendiconti*, Palermo, 1907, p. 34.

⁶Fürstenau, *Darstellung der reellen Wurzeln algebraischer Gleichungen durch Determinanten der Coefficienten*, program dissertation, Marburg, 1860; *Neue Methode zur Darstellung und Berechnung der imaginären Wurzeln algebraischer Gleichungen durch Determinanten der Coefficienten*, program dissertation, Marburg, 1867.

H. Naegelsbach, moreover, everything reduces to the fact that the function

$$R(x) = \frac{1}{c_0 + c_1x + \cdots + c_mx^m}$$

has the power-series expansion

$$R(x) = \frac{1}{c_0} - \frac{\Delta_1}{c_0^2}x + \frac{\Delta_2}{c_0^3}x^2 - \frac{\Delta_3}{c_0^4}x^3 + \cdots .^7$$

Indeed, let α be the root in question and let A be the residue of $R(x)$ at α . Since the poles of the rational fraction

$$r(x) = R(x) - \frac{A}{1 - x/\alpha}$$

are farther from the origin than the point α , the series

$$r(x) = \frac{1}{c_0} - A + \left(-\frac{\Delta_1}{c_0^2} - \frac{A}{\alpha}\right)x + \left(\frac{\Delta_2}{c_0^3} - \frac{A}{\alpha^2}\right)x^2 + \cdots$$

converges for $x = \alpha$; in particular its terms tend to zero, and therefore

$$\frac{\Delta_n(-\alpha)^n}{c_0^{n+1}} \longrightarrow A.$$

It follows that

$$-c_0 \frac{\Delta_{n-1}}{\Delta_n} = \alpha \frac{\Delta_{n-1}(-\alpha)^{n-1}/c_0^n}{\Delta_n(-\alpha)^n/c_0^{n+1}} \longrightarrow \alpha.$$

Fürstenau's method extends immediately to transcendental equations. Observe also that, if for brevity we write

$$R(x) = a_0 + a_1x + a_2x^2 + \cdots ,$$

our result becomes

$$\alpha = \lim_{n \rightarrow \infty} \frac{a_{n-1}}{a_n}.$$

This elementary and well-known result concerns the power-series expansion of any function having a simple pole α , all its other singular points being farther

⁷Naegelsbach, *Studien zu Fürstenaus neuer Methode der Darstellung und Berechnung der Wurzeln algebraischer Gleichungen durch Determinanten der Coefficienten*, *Archiv für Mathematik und Physik*, vol. LIX, 1876, pp. 147–192.

$x_{n+1}, x_{n+2}, \dots$ are successively eliminated. This procedure yields an expansion of the form

$$x_n = B_{n,n}\beta_n + B_{n,n+1}\beta_{n+1} + \dots,$$

where the B are expressions formed from the coefficients b_{ik} and readily calculated by determinants.

It is easy to see that Kötteritzsch's method is at bottom the same as Fourier's; it differs only in containing a formal computational procedure that may be convenient in certain cases. From the standpoint of infinity, however, the two methods do not differ. On this point Kötteritzsch teaches us nothing new; he merely says that for large indices the terms must be very small, so that they may be neglected.

Finally, Kötteritzsch applies his method to several special cases and extends to them formulas known for finite systems. Here too, however, almost everything rests on analogy.¹¹

Appell's Note and Poincaré's Criticism

13. Poincaré deserves the credit for making the first critical investigations of our subject. His attention was drawn to it by the works of Hill (1877) and Appell (1885). We shall return later to Hill's method.

Appell proposes to expand the elliptic function θ_1/θ in a trigonometric series

¹¹Mention should be made here of a paper by von Koch which was to appear in the *Proceedings of the International Congress at Cambridge, 1912*. Von Koch studies systems of type (12) under very broad conditions. I confine myself to stating one special result, connected among other things with Fürstenau's problem. Let $f(z) = 1 + c_1z + c_2z^2 + \dots$ be an entire function, and let α be the zero nearest the origin. Further, let $x_1, x_2, \dots$ be a solution of

$$\begin{aligned} 0 &= x_0 + c_1x_1 + c_2x_2 + c_3x_3 + \dots, \\ 0 &= x_1 + c_1x_2 + c_2x_3 + c_3x_4 + \dots, \\ &\dots \end{aligned}$$

Then $\limsup_{n \rightarrow \infty} |x_n|^{1/n} \geq |\alpha|$. See also Borel's thesis, discussed below, and Stäckel, "Periodische Funktionen und Systeme von unendlich vielen linearen Gleichungen," *Festschrift H. Weber, 1912*, pp. 396–409.

by the method of undetermined coefficients.¹² In Jacobi's notation,

$$\theta\left(\frac{Kx}{\pi i}\right) = \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{nx}, \quad \theta_1\left(\frac{Kx}{\pi i}\right) = \sum_{n=-\infty}^{\infty} q^{n^2} e^{nx}, \quad q = e^{-\pi K'/K};$$

the periods $2K$ and $2iK'$ are arranged so that the real part of K'/K is positive and hence $|q| < 1$. One seeks the coefficients Λ_n in the expansion

$$\frac{\theta_1(Kx/\pi i)}{\theta(Kx/\pi i)} = \sum_{n=-\infty}^{\infty} \Lambda_n e^{nx}.$$

After clearing the denominator, multiplying out the right-hand side, and equating the coefficients of e^{nx} for every n , one obtains

$$q^{n^2} = \sum_{\mu=-\infty}^{\infty} (-1)^{n-\mu} q^{(n-\mu)^2} \Lambda_{\mu} \quad (n = 0, 1, 2, \dots),$$

or, after simplification,

$$(-1)^n = \sum_{\mu=-\infty}^{\infty} (-1)^{\mu} q^{\mu^2 - 2\mu n} \Lambda_{\mu} \quad (n = 0, 1, 2, \dots).$$

Since the quotient θ_1/θ is even, $\Lambda_{-\mu} = \Lambda_{\mu}$; consequently the system reduces to^a

$$(-1)^n = \Lambda_0 + \sum_{\mu=1}^{\infty} (-1)^{\mu} q^{\mu^2} (q^{2n\mu} + q^{-2n\mu}) \Lambda_{\mu} \quad (n = 0, 1, 2, \dots).$$

Putting

$$\omega = \frac{2\pi K' i}{K},$$

the system becomes

$$(-1)^n = \Lambda_0 + 2 \sum_{\mu=1}^{\infty} (-1)^{\mu} q^{\mu^2} \Lambda_{\mu} \cos(n\mu\omega) \quad (n = 0, 1, 2, \dots).$$

¹²Appell, "Sur une méthode élémentaire pour obtenir les développements en séries trigonométriques des fonctions elliptiques," *Bulletin de la Société mathématique de France*, vol. XIII (1885), pp. 13–18.

^a*Translator's note:* The French text calls both θ_1 and θ odd. The displayed bilateral series show that each is even; only the evenness of their quotient is used here.

To solve this system, Appell uses the principle of sections: he takes the first $m + 1$ equations, retains in them only the first $m + 1$ unknowns, suppresses every term depending on the others, and finally lets m increase indefinitely. If $\Lambda_0^{(m)}, \Lambda_1^{(m)}, \dots, \Lambda_m^{(m)}$ is the solution of the reduced system, then

$$\Lambda_0^{(m)} = \frac{\Delta(\pi, \omega, 2\omega, \dots, m\omega)}{\Delta(0, \omega, 2\omega, \dots, m\omega)},$$

and, for $\mu > 0$,

$$(-1)^\mu q^{\mu^2} \Lambda_\mu^{(m)} = \frac{\Delta[0, \omega, \dots, (\mu - 1)\omega, \pi, (\mu + 1)\omega, \dots, m\omega]}{\Delta(0, \omega, 2\omega, \dots, m\omega)},$$

where

$$\Delta(a, b, \dots, l) = \begin{vmatrix} 1 & 1 & \cdots & 1 \\ \cos a & \cos b & \cdots & \cos l \\ \vdots & \vdots & & \vdots \\ \cos ma & \cos mb & \cdots & \cos ml \end{vmatrix} = C \prod (\cos a - \cos b).$$

Here C is a numerical constant, and the product extends over all pairwise differences among $\cos a, \cos b, \dots, \cos l$. Returning from ω to q , one obtains

$$\Lambda_0^{(m)} = \prod_{v=1}^m \frac{(1 + q^{2v})^2}{(1 - q^{2v})^2},$$

$$\Lambda_\mu^{(m)} = \frac{2q^\mu}{1 + q^{2\mu}} \frac{\prod_{v=1}^m (1 + q^{2v})^2}{\prod_{v=1}^{m-\mu} (1 - q^{2v}) \prod_{v=1}^{m+\mu} (1 - q^{2v})}.$$

Finally, on letting the index m increase indefinitely, one obtains

$$\Lambda_0 = \prod_{v=1}^{\infty} \frac{(1 + q^{2v})^2}{(1 - q^{2v})^2} = \frac{\pi}{2qK} \sqrt{\frac{1}{k'}}, \quad \Lambda_\mu = \frac{2q^\mu}{1 + q^{2\mu}} \Lambda_0.$$

Thus one recovers the known expansion

$$\frac{\theta_1(z)}{\theta(z)} = \frac{\pi}{2qK} \sqrt{\frac{1}{k'}} \left(1 + 4 \sum_{\mu=1}^{\infty} \frac{q^\mu}{1 + q^{2\mu}} \cos \frac{\mu\pi z}{K} \right).$$

14. In the same *Bulletin* that contained Appell's note just discussed, immediately following it, appeared Poincaré's first critical remarks.¹³ He asks in what cases the method that succeeded for Appell may legitimately be used; that is, he examines, in certain cases, the legitimacy of the principle of sections.

He first considers the system

$$\sum_{k=1}^{\infty} a_k^i x_k = 0 \quad (i = 0, 1, 2, \dots), \quad (13)$$

assuming $|a_{k+1}| > |a_k|$ and $|a_k| \rightarrow \infty$ as $k \rightarrow \infty$, and seeks to satisfy it in such a way that the series on the left converge.

His method rests entirely on the elements of the Theory of Functions. Form the entire function $F(z)$ having the numbers a_k as simple zeros and having no other zeros. Since Weierstrass we have known that, under the hypothesis $|a_k| \rightarrow \infty$, such functions exist and may be calculated by infinite products. For definiteness, suppose that $\sum 1/|a_k|$ converges; then put

$$F(z) = \prod_{k=1}^{\infty} \left(1 - \frac{z}{a_k}\right).$$

Let $C_1, C_2, \dots, C_k, \dots$ be infinitely many circles centered at the origin, such that C_k separates the points $z = a_k$ and $z = a_{k+1}$. Suppose that

$$\int_{C_k} \frac{z^i dz}{F(z)} \rightarrow 0 \quad (k \rightarrow \infty), \quad (14)$$

for every i . By Cauchy's theorem the preceding relation may be written

$$\sum_{k=1}^{\infty} a_k^i A_k = 0,$$

where A_k denotes the residue of $1/F(z)$ at $z = a_k$. Thus, under the hypothesis made, the residues of $1/F(z)$ furnish a solution of system (13). Now

$$A_k = \frac{-a_k}{(1 - a_k/a_1) \cdots (1 - a_k/a_{k-1})(1 - a_k/a_{k+1}) \cdots},$$

and this is the same solution to which the principle of sections would lead.

¹³Poincaré, "Remarques sur l'emploi de la méthode précédente," *Bulletin de la Société mathématique de France*, vol. XIII (1885), pp. 19–27.

15. Fourier's system (4) falls in principle within the type just considered. Indeed, omitting its first equation and putting

$$(2m-1)^2 = b_m, \quad (2m-1)^2 a_m = x_m,$$

the system becomes

$$\sum_{m=1}^{\infty} b_m^i x_m = 0 \quad (i = 0, 1, 2, \dots),$$

and the b_m increase indefinitely. Let us calculate $F(z)$. We have

$$F(z) = \prod_{m=1}^{\infty} \left[1 - \frac{z}{(2m-1)^2} \right] = \cos \frac{\pi}{2} \sqrt{z}.$$

The residues of $1/F(z)$ are^b

$$B_m = \frac{1}{F'(b_m)} = -\frac{4}{\pi} \frac{\sqrt{b_m}}{\sin(\frac{\pi}{2} \sqrt{b_m})} = \pm \frac{4}{\pi} (2m-1).$$

Thus, apart from a factor, they represent Fourier's solution.

It is not, however, a solution of the kind Poincaré required: the series $\sum b_m^i B_m$ do not converge. This example shows very clearly that hypothesis (14) cannot be omitted.

16. Here is a very interesting observation of Poincaré, which at first sight will appear paradoxical. Suppose that a solution $x_1 = \alpha_1, x_2 = \alpha_2, \dots$ of system (13) has been found, and suppose also that the α_k do not vanish. Let p be any positive integer. It is clear that $x_1 = a_1^p \alpha_1, x_2 = a_2^p \alpha_2, \dots$ also satisfy system (13). The same is true of $x_1 = f(a_1) \alpha_1, x_2 = f(a_2) \alpha_2, \dots$, where $f(z)$ is any polynomial. So far this is correct. Now consider, in place of polynomials, the entire function

$$f(z) = c_0 + c_1 z + c_2 z^2 + \dots.$$

Multiply the equations (13), beginning with the $(i+1)$ st, successively by $c_0, c_1, c_2, \dots$, and add term by term; this would give

$$\sum_{k=1}^{\infty} a_k^i f(a_k) \alpha_k = 0 \quad (i = 0, 1, 2, \dots). \quad (15)$$

^b*Translator's note:* The French original prints the factor $\pi/4$ in both places; it is corrected here to $4/\pi$, as follows by differentiating $F(z) = \cos((\pi/2)\sqrt{z})$.

The following paradoxical consequence would then follow at once: if the reasoning were correct, every arbitrary sequence $\beta_1, \beta_2, \dots$ would satisfy system (13). Indeed, one can choose the entire function $f(z)$ so that at $z = a_1, a_2, a_3, \dots$ it takes respectively the values $\beta_1/\alpha_1, \beta_2/\alpha_2, \beta_3/\alpha_3, \dots$. To obtain such a function, let $F(z)$ be the entire function already considered, vanishing at $z = a_1, a_2, \dots$ and having no other zeros. By Mittag-Leffler's theorem, one can construct a meromorphic function $R(z)$ having the a_k as simple poles with residues $\beta_k/[\alpha_k F'(a_k)]$, and no other poles. Thus $f(z) = F(z)R(z)$ is the required entire function. Applied to this $f(z)$, formulas (15) give

$$\sum_{k=1}^{\infty} a_k^i \beta_k = 0 \quad (i = 0, 1, 2, \dots).$$

If the reasoning were legitimate, these equations would have to hold for every choice of the quantities β_k . Obviously it is not legitimate, for in general it is not permissible to add infinitely many series term by term.

To make the reasoning valid, assume that for the solution $x_1 = \alpha_1, x_2 = \alpha_2, \dots$ the left-hand sides of equations (13) are absolutely convergent series. Put

$$\sum_{k=1}^{\infty} |a_k^i \alpha_k| = S_i \quad (i = 0, 1, 2, \dots).$$

Then whenever the series

$$|c_0|S_0 + |c_1|S_1 + |c_2|S_2 + \dots$$

converges, our argument is valid, since termwise addition is permitted. Since $f(z)$ depends only on the quantities a_k, α_k, β_k , its coefficients c_k will be expressible in some definite way through those same quantities. Everything therefore reduces to the convergence of a certain series whose terms are well-determined functions of the a_k, α_k , and β_k . When that series converges, the β_k give a solution of system (13). Thus we have connected the problem of solving system (13), to a certain extent, with a simple question of convergence.

17. The equations treated by Appell do not belong to the type just considered, but to the type

$$\sum_{k=-\infty}^{\infty} a_k^i x_k = 0 \quad (i = 0, 1, 2, \dots),$$

where $|a_k|$ increases toward ∞ as $k \rightarrow \infty$ and decreases toward 0 as $k \rightarrow -\infty$. To treat this type, Poincaré uses a method analogous to that of no. 14; the principal

difference is that the function $F(z)$ having the a_k as zeros is no longer an entire function, since the origin, being a limit point of the a_k , is necessarily an essential singular point.

The detailed study of Poincaré's note and of the supplementary remarks that followed it in a second note¹⁴ would require us to penetrate still further into the Theory of Functions. Besides, the matter there is not one of methods in the strict sense; rather, these are ideas still awaiting development.¹⁵

What I have said, however, applies only to the first note and to the first part of the second. In the second part, abruptly leaving the line of ideas followed thus far, Poincaré lays the first foundations of a theory of infinite determinants, which will form the subject of the [next chapter](#).

¹⁴Poincaré, "Sur les déterminants d'ordre infini," *Bulletin de la Société mathématique de France*, vol. XIV (1886), pp. 77–90.

¹⁵The only progress in this direction is due to Borel. He was led to it by the following problem treated in his thesis, "Sur quelques points de la Théorie des fonctions," *Annales de l'École Normale supérieure*, 3rd series, vol. XII (1895), pp. 9–55: determine a power series $f(z) = \sum b_n z^n$ convergent for $z = 1$ together with its derivatives, prescribed values $f^{(n)}(1) = F_n$ being given for the series and its derivatives at $z = 1$. The essential idea of Borel's reasoning is this: to solve the equations $f^{(n)}(1) = F_n$, it is enough to know how to solve them with a certain approximation. Suppose a power series $g(z) = \sum b_n z^n$ has been found such that $|g^{(n)}(1) - F_n| < C$ for all n . Put $g^{(n)}(1) - F_n = c_n$; then $\sum (c_n/n!)(z-1)^n$ defines an entire function $h(z)$ and $f(z) = g(z) - h(z)$. Thus everything reduces to solving $f^{(n)}(1) = F_n$ with the stated approximation. Put $b_0 = 0$, $b_k = \pm 1/k$ for $k = 1, 2, \dots, n$, choosing the signs and n so that $|b_1 + \dots + b_n - F_0| < 1$. Next put $b_k = \pm 1/k^2$ for $k = n+1, \dots, n'$, choosing the signs and n' so that $|b_1 + 2b_2 + \dots + n'b_{n'} - F_1| < 1$. Then put $b_k = \pm 1/k^3$ for $k = n'+1, \dots, n''$, so that

$$|2b_2 + 2 \cdot 3b_3 + \dots + (n''-1)n''b_{n''} - F_2| < 1.$$

Continued in this fashion, the procedure leads to a function $g(z)$ such that $|g^{(n)}(1) - F_n| < 3$. This follows readily from the divergence of $\sum 1/k$ and the inequality $\sum 1/k^2 < 2$. The reasoning assumes the data F_n real, but this hypothesis is plainly inessential.

Borel applies an analogous procedure to the systems

$$\sum_{k=1}^{\infty} a_k^i x_k = A_i \quad (i = 1, 2, \dots),$$

where a_k increases indefinitely with k . The procedure consists in putting, according to the indices, $x_k = \pm 1/k, \pm 1/(ka_k), \pm 1/(ka_k^2), \dots$, so that the quantities $B_i = A_i - \sum a_k^i x_k$ remain bounded as a whole. Thus the general case may be reduced to the special case in which the quantities A_i are bounded. In this special case Borel solves the system by slightly modifying Poincaré's idea from [no. 14](#). Let $F(z)$ have the a_k as simple zeros, and choose θ_k so that the series $\sum |a_k^i/[F'(a_k)\theta_k]|$ converge. Construct an entire function $\theta(z)$ such that $\theta(a_k) = \theta_k$. On writing

$$\frac{F(z)\theta(z)}{z - a_k} = \sum c_n^{(k)} z^n,$$

a solution is given by

$$x_k = \frac{\sum_i c_i^{(k)} A_i}{F'(a_k)\theta_k}.$$

Chapter II.

Infinite Determinants

Historical Remarks and Generalities

18. The extension of algebraic methods to systems of linear equations with infinitely many unknowns naturally led to the consideration of infinite determinants. Allusions to these algorithms already occur in the work of Kötteritzsch cited above. Their introduction is generally attributed to G. W. Hill. That eminent astronomer used them in a very important memoir on the motion of the lunar perigee,¹ and it was through this memoir that Poincaré's attention was drawn to the matter. Hill considers the equation

$$\frac{d^2w}{dt^2} + \theta w = 0, \quad (1)$$

where θ is a series of the form

$$\theta = \theta_0 + 2\theta_1 \cos t + 2\theta_2 \cos 2t + \cdots.$$

Putting $\theta_{-n} = \theta_n$, one may also write

$$\theta = \sum_{n=-\infty}^{\infty} \theta_n e^{int}. \quad (2)$$

The general integral of equation (1) may be put in the form

$$w = \sum_{n=-\infty}^{\infty} b_n e^{i(n+c)t},$$

¹Hill, *On the Part of the Motion of the Lunar Perigee Which Is a Function of the Mean Motions of the Sun and Moon*, Cambridge, Massachusetts, U.S.A., 1877 (reprinted in *Acta Mathematica*, vol. VIII, 1886, p. 1). Compare also Adams's communication in the *London Astronomical Society Monthly Notices*, vol. XXXVIII (1877), p. 13; there he announces that his earlier study of the motion of the Moon's node had already led him to an infinite determinant, but he did not publish his results.

where the b_n and c are suitably chosen constants. Substituting this series for w and series (2) for θ in equation (1), and comparing coefficients, gives infinitely many equations

$$\sum_{k=-\infty}^{\infty} \theta_{n-k} b_k - (n+c)^2 b_n = 0 \quad (n = -\infty, \dots, +\infty), \quad (3)$$

and one must determine the b_n and c so that these equations are satisfied.

Hill treats system (3) by the procedure most often used for finite systems, namely by determinants. He introduces *infinite determinants*, applies to them the ordinary rules of determinant calculus, and his boldness is justified by success, since the results agree with observation. He did not, however, prove the legitimacy of his method. This gap was soon filled by Poincaré, who on this occasion developed the first principles of a theory of infinite determinants.² Poincaré's investigations were continued until recent times and greatly deepened by von Koch, to whom, one may say, almost all the essential results of the theory are due.³

19. Consider the system

$$\sum_{k=1}^{\infty} a_{ik} x_k = c_i \quad (i = 1, 2, \dots), \quad (4)$$

and suppose that the principle of sections may legitimately be applied to it. Suppose further that, for all sufficiently large n ,

$$\Delta_n = \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} \neq 0.$$

Then the unknown x_k is given by

$$\lim_{n \rightarrow \infty} \frac{\Delta_n^{(k)}}{\Delta_n},$$

²See the note cited at [no. 17](#), or the same author's *Méthodes nouvelles de la Mécanique céleste*, vol. II, p. 260.

³For a list of von Koch's works on infinite determinants, compare his report "Sur les systèmes d'une infinité d'équations linéaires à une infinité d'inconnues," *Proceedings of the Congress of Mathematicians held at Stockholm*, 1909. Add to that list the two notes "Sur un nouveau critère de convergence pour les déterminants infinis," *Arkiv för matematik, astronomi och fysik*, vol. VII (1911), no. 4, and "Sur certains systèmes d'équations linéaires à une infinité d'inconnus," *ibid.*, vol. VIII (1912), no. 9, together with the communication mentioned at [no. 12](#).

where $\Delta_n^{(k)}$ denotes the result of replacing the terms of column k of Δ_n by $c_1, \dots, c_n$. It may happen that the denominator Δ_n itself tends, as $n \rightarrow \infty$, to a limit Δ ; if this limit is nonzero, one can assert that the numerator also tends to a limit $\Delta^{(k)}$ and that

$$x_k = \frac{\Delta^{(k)}}{\Delta}.$$

This, however, is only the simplest case; the homogeneous system (3) does not belong to it and requires a more delicate discussion. To approach that system by infinite determinants, these determinants must be studied somewhat more closely. It should also be observed that even in the simpler case just considered we assumed *a priori* that the principle of sections applies. This is not self-evident and may in fact fail; the limits $\Delta \neq 0$ and $\Delta^{(k)}$ ($k = 1, 2, \dots$) may exist without the values $x_k = \Delta^{(k)}/\Delta$ satisfying system (4). For example, if $a_{ik} = 0$ for $k < i$ and $a_{ik} = 1$ for $k \geq i$, while $c_i = (-1)^i$, then $\Delta = 1$ and $\Delta^{(k)} = 2(-1)^k$, which gives $x_k = 2(-1)^k$; when these values are substituted in equations (4), the left-hand sides diverge.⁴

These remarks suffice to show that, if one wishes to base a theory of infinite systems of equations on the study of infinite determinants, the conditions under which one is working must first be clearly specified. Well-chosen hypotheses will make it possible to extend to infinite determinants the ordinary rules for determinants of finite order and consequently to apply them to the theory with which we are concerned.

Some of the simplest rules undoubtedly extend at once to all infinite determinants. For example, rows and columns may be interchanged; interchanging two rows amounts to multiplying the determinant by -1 ; multiplying all elements of one row by the same number amounts to multiplying the determinant itself by that number; the determinant vanishes if two of its rows coincide; it is unchanged when the elements of one row are increased by the corresponding elements of another, and so forth. All this follows immediately from the analogous properties of finite-order determinants.

⁴Cazzaniga gave a series of examples of this kind, showing the care required with infinite determinants: "Sui determinanti d'ordine infinito," *Annali di Matematica*, 2nd series, vol. XXVI (1897), pp. 143–218; "Intorno ad un tipo di determinanti nulli d'ordine infinito," *ibid.*, 3rd series, vol. I (1898), pp. 83–94.

Normal Determinants

20. Consider the doubly indexed array

$$\begin{array}{cccc} 1 + a_{11}, & a_{12}, & a_{13}, & \dots, \\ a_{21}, & 1 + a_{22}, & a_{23}, & \dots, \\ a_{31}, & a_{32}, & 1 + a_{33}, & \dots, \\ \vdots & \vdots & \vdots & \end{array}$$

and suppose that the doubly infinite series $\sum_{i,k=1}^{\infty} |a_{ik}|$ converges. Put

$$\Lambda_k = \sum_{i=1}^{\infty} |a_{ik}|;$$

by hypothesis $\sum_{k=1}^{\infty} \Lambda_k$ converges. A well-known convergence rule then implies that the products

$$\Pi_n = \prod_{k=1}^n (1 + \Lambda_k)$$

tend, as $n \rightarrow \infty$, to a limit Π .

Now compare the two determinants

$$\Delta_n = \begin{vmatrix} 1 + a_{11} & a_{12} & \cdots & a_{1n} \\ \vdots & \vdots & & \vdots \\ a_{n1} & a_{n2} & \cdots & 1 + a_{nn} \end{vmatrix},$$

$$\Delta_{n+p} = \begin{vmatrix} 1 + a_{11} & a_{12} & \cdots & a_{1,n+p} \\ \vdots & \vdots & & \vdots \\ a_{n+p,1} & a_{n+p,2} & \cdots & 1 + a_{n+p,n+p} \end{vmatrix}.$$

They are sums of certain products of the quantities a_{ik} with appropriate signs. The same products occur in absolute value in the expansions of Π_n and Π_{n+p} in powers of the $|a_{ik}|$. Moreover, Δ_{n+p} contains all terms of Δ_n , and its other terms occur in absolute value in the expansion of $\Pi_{n+p} - \Pi_n$. Hence

$$|\Delta_n| \leq \Pi_n, \quad |\Delta_{n+p} - \Delta_n| \leq \Pi_{n+p} - \Pi_n;$$

consequently the series

$$\Delta_1 + (\Delta_2 - \Delta_1) + (\Delta_3 - \Delta_2) + \cdots$$

converges absolutely to a quantity $\Delta = \lim \Delta_n$ such that $|\Delta| \leq \Pi$.

21. Replace in our array the elements of column k by quantities c_i , assumed bounded as a whole, that is, bounded in absolute value by some quantity C . Let $n > k$, and denote by $\Delta_n^{(k)}$ the result of applying the indicated modification to Δ_n , and by $\Pi_n^{(k)}$ the result of suppressing the factor $1 + \Lambda_k$ from Π_n . The terms of $\Delta_n^{(k)}$ and of $\Delta_{n+p}^{(k)} - \Delta_n^{(k)}$ occur, in absolute value and apart from a factor $|c_i|$, in the expansions of $\Pi_n^{(k)}$ and $\Pi_{n+p}^{(k)} - \Pi_n^{(k)}$. Hence

$$|\Delta_n^{(k)}| \leq C \Pi_n^{(k)}, \quad |\Delta_{n+p}^{(k)} - \Delta_n^{(k)}| \leq C(\Pi_{n+p}^{(k)} - \Pi_n^{(k)}).$$

Thus the determinant $\Delta^{(k)} = \lim \Delta_n^{(k)}$ converges and $|\Delta^{(k)}| \leq C \Pi$.

In particular, put $c_i = 1$ and $c_j = 0$ for $j \neq i$; $\Delta^{(k)}$ then becomes what is called the minor $\binom{i}{k}$ of the determinant Δ_n . Similarly, we shall call $\Delta^{(k)}$ the minor $\binom{i}{k}$ of Δ . It follows at once from the analogous fact for finite determinants that the minor $\binom{i}{k}$ is unchanged if the elements of row i , except the k th, are replaced by zeros or by arbitrary quantities. This observation shows that rows and columns play the same role in forming minors.

We shall prove the following theorem, whose first part is the familiar Laplace rule.

Theorem. *Whatever the quantities c_i , provided they are bounded as a whole,*

$$\Delta^{(k)} = \sum_{i=1}^{\infty} \binom{i}{k} c_i, \tag{5}$$

and the series on the right converges absolutely. In particular, the series

$$\sum_{i=1}^{\infty} \left| \binom{i}{k} \right| \tag{6}$$

converges, and its sum does not exceed Π .

Proof. Absolute convergence of the series on the right of (5) follows immediately from convergence of (6). Since the latter series has positive terms, it is enough to prove that its partial sums do not exceed a finite bound. I claim that they do not exceed Π . In $\Delta^{(k)}$ put

$$c_i = \operatorname{sgn}^* \binom{i}{k} \quad (i \leq n), \quad c_i = 0 \quad (i > n),$$

where $\text{sgn}^* z$ denotes 0 when $z = 0$ and $|z|/z$ otherwise.⁵ Then $C = 1$, and $\Delta^{(k)}$ is the sum of the first n terms of (6); the inequality $|\Delta^{(k)}| \leq C\Pi$ therefore shows that this sum cannot exceed Π .

It remains to verify identity (5). The sum s_n of the first n terms of the series on the right is the result of replacing by zeros in $\Delta^{(k)}$ the c_i beginning with c_{n+1} . Hence the difference $\Delta^{(k)} - s_n$ is what $\Delta^{(k)}$ becomes after its first n quantities c_i have been set equal to zero. Denote this last determinant by $\Delta^{(k,n)}$, and let $\Delta_n^{(k,n)}$ be the finite determinant formed from its first n^2 elements. Then

$$|\Delta^{(k,n)} - \Delta_n^{(k,n)}| \leq C(\Pi - \Pi_n).$$

For $n \geq k$, however, $\Delta_n^{(k,n)}$ vanishes because it contains an entire column of zeros. Hence

$$|\Delta^{(k)} - s_n| = |\Delta^{(k,n)}| \leq C(\Pi - \Pi_n).$$

As $n \rightarrow \infty$, $\Pi - \Pi_n \rightarrow 0$, and therefore $s_n \rightarrow \Delta^{(k)}$, as required. $\square$

We record the following special cases of (5):

$$\binom{j}{k} + \sum_{i=1}^{\infty} a_{ij} \binom{i}{k} = \begin{cases} \Delta, & k = j, \\ 0, & k \neq j. \end{cases} \quad (7)$$

Convergence of (6) also immediately implies absolute convergence of the double series

$$\sum_{i,k=1}^{\infty} a_{jk} c_i \binom{i}{k}. \quad (8)$$

Throughout the preceding discussion, rows and columns may exchange their roles. In particular,

$$\binom{i}{j} + \sum_{k=1}^{\infty} a_{jk} \binom{i}{k} = \begin{cases} \Delta, & i = j, \\ 0, & i \neq j. \end{cases} \quad (9)$$

22. Infinite determinants Δ of the type just considered are called *normal determinants*. Historically, Poincaré studied the determinants Δ and $\Delta^{(k)}$ under the additional restrictive condition $a_{ii} = 0$ for all i . It is nearly evident that the type considered here is easily reduced to that more special type. For example, when $a_{ii} \neq -1$, one need only divide column i by $1 + a_{ii}$. Such a reduction is

⁵Thus, if $z = re^{i\varphi}$, then $\text{sgn}^* z = e^{-i\varphi}$. For real positive or negative z , $\text{sgn}^* z = \pm 1$, according to the sign of z .

that is, the quantities (11) satisfy system (10). Moreover, the inequalities

show that these quantities remain bounded in absolute value.

Solution (11) is unique: more precisely, system (10) has no other solution with the required boundedness property. Otherwise the homogeneous system

would also have a bounded solution $x_1, x_2, \dots$ in which at least one x_i did not vanish. But the following double series converge absolutely, and hence

so $x_j = 0$ for every j .

Second case: $\Delta = 0$. The homogeneous system (12) has the solution

where i is any index. This is an immediate consequence of formulas (9).

Suppose i and k are chosen so that the minor $\binom{i}{k} \neq 0$. Then solution (13) differs from the evident solution $x_1 = x_2 = \dots = 0$ and is, moreover, unique up to a factor. Indeed, suppose the system has the solution $x_1 = \xi_1, x_2 = \xi_2, \dots$, and replace its i th equation by

$$x_k = \xi_k.$$

The determinant of the new system is $\binom{i}{k} \neq 0$; hence the system belongs to the first case and has the unique solution

$$x_1 = \frac{\binom{i}{1}}{\binom{i}{k}} \xi_k, \quad x_2 = \frac{\binom{i}{2}}{\binom{i}{k}} \xi_k, \quad \dots$$

24. It may happen, however, that all the minors $\binom{i}{k}$ vanish. To discuss this case, one must first extend the notion of a minor by introducing, with von Koch, minors

$$\binom{i_1, \dots, i_r}{k_1, \dots, k_r}$$

of order r . By this we mean the result of replacing in Δ the r elements lying simultaneously in row i_p and column k_p ($p = 1, \dots, r$) by 1, and all other elements of these rows (or, equivalently, of these columns) by zero. Our general convergence rule applies also to these new determinants.

von Koch's Theorem. *There is always a minor of Δ of some finite order that does not vanish. In particular, if m is sufficiently large, the minor*

$$\binom{1, \dots, m}{1, \dots, m}$$

is certainly nonzero.

Proof. Choose m such that

$$R_m = \sum_{i=m+1}^{\infty} \Lambda_i < \frac{1}{2}.$$

Then

$$\left| \binom{1, \dots, m}{1, \dots, m} \right| \geq 1 - \sum_{i=m+1}^{\infty} \Lambda_i - \sum_{i,k=m+1}^{\infty} \Lambda_i \Lambda_k - \dots \geq 1 - R_m - R_m^2 - \dots = \frac{1 - 2R_m}{1 - R_m} > 0.$$

□

25. By the theorem just proved, in the case now under consideration there is a number r such that Δ and all its minors of orders $1, \dots, r-1$ vanish, while at least one minor of order r is nonzero. Let

$$D = \binom{i_1, \dots, i_r}{k_1, \dots, k_r} \neq 0$$

be such a minor. In (12), replace the r equations corresponding to $i_1, \dots, i_r$ by

$$x_{k_1} = \xi_{k_1}, \quad x_{k_2} = \xi_{k_2}, \quad \dots, \quad x_{k_r} = \xi_{k_r}.$$

The determinant of the modified system is $D \neq 0$, so the system belongs to the first case and has the unique solution

$$x_k = \frac{1}{D} \sum_{p=1}^r \begin{pmatrix} i_1, \dots, i_r \\ k_1, \dots, k_{p-1}, k, k_{p+1}, \dots, k_r \end{pmatrix} \xi_{k_p}. \quad (14)$$

Give arbitrary values to the indeterminates $\xi_{k_1}, \dots, \xi_{k_r}$. The resulting x_k satisfy the homogeneous equations (12), except perhaps those corresponding to $i_1, \dots, i_r$, which were temporarily excluded. But the minors

$$\begin{pmatrix} i_1, \dots, i_{p-1}, i, i_{p+1}, \dots, i_r \\ k_1, \dots, k_{p-1}, k, k_{p+1}, \dots, k_r \end{pmatrix},$$

of order r with respect to Δ , are at the same time first-order minors of the determinant obtained by suppressing the other $r - 1$ selected rows and columns. Hence, by (9),

$$\begin{aligned} & \begin{pmatrix} i_1, \dots, i, \dots, i_r \\ k_1, \dots, i, \dots, k_r \end{pmatrix} + \sum_k a_{ik} \begin{pmatrix} i_1, \dots, i, \dots, i_r \\ k_1, \dots, k, \dots, k_r \end{pmatrix} \\ &= \begin{pmatrix} i_1, \dots, i_{p-1}, i_{p+1}, \dots, i_r \\ k_1, \dots, k_{p-1}, k_{p+1}, \dots, k_r \end{pmatrix} = 0, \end{aligned}$$

where i and the summation indices are first assumed distinct from the fixed indices. The summation may be extended to all k , and the formula is valid for all i , if by definition one sets

$$\begin{pmatrix} i_1, \dots, i_r \\ k_1, \dots, k_r \end{pmatrix} = 0$$

whenever two i -indices or two k -indices coincide. Substituting successively $k = k_1, \dots, k_r$ in this formula, multiplying respectively by $\xi_{k_1}, \dots, \xi_{k_r}$, and adding term by term, equation (14) gives

$$x_i + \sum_{k=1}^{\infty} a_{ik} x_k = 0$$

for every i .

Thus homogeneous system (12) has the solutions (14), depending on r parameters, and no others.

Now consider the nonhomogeneous system (10) and suppose that it has a solution $x'_1, x'_2, \dots$. Any solution of homogeneous system (12) may plainly be added to it. Add in particular the solution corresponding to $\xi_{k_1} = -x'_{k_1}, \dots, \xi_{k_r} = -x'_{k_r}$; the resulting solution $x''_1, x''_2, \dots$ of (10) has $x''_{k_1} = \dots = x''_{k_r} = 0$. Thus, whenever (10) has solutions, one of them has $x_{k_1} = \dots = x_{k_r} = 0$, and all the others are obtained from it by adding the solutions (14) of the homogeneous system.

It remains, then, to determine a solution (x_k) of (10) with $x_{k_1} = \dots = x_{k_r} = 0$. The other unknowns then satisfy the system obtained from (10) by suppressing the equations numbered $i_1, \dots, i_r$ and the unknowns $x_{k_1}, \dots, x_{k_r}$. The determinant of this modified system is $D \neq 0$, so it has exactly one solution. Hence (10) is solvable if and only if the values $x_{k_1} = \dots = x_{k_r} = 0$, together with the values of the remaining x_k furnished by the modified system, satisfy the equations of ranks $i_1, \dots, i_r$. This gives r relations among the right-hand sides of (10); these relations express the necessary and sufficient condition for solvability.

This condition can be put into several forms analogous to those known for ordinary finite systems. We shall not dwell on them. The essential fact resulting from the preceding considerations is that the classical theory of determinants extends to normal infinite determinants and to the corresponding systems of equations.

Absolutely Convergent Determinants

26. In seeking to extend the preceding results to more general cases, von Koch soon observed that a very slight modification of the reasoning yields a considerable extension.⁶ The majorant expression Π is in fact much richer in terms than the determinant Δ : it contains all products of the $|a_{ik}|$ whose factors belong to distinct columns. Von Koch's procedure consists in constructing a majorant expression better adapted to the structure of determinants. He starts from the following definition.

Let a doubly indexed array (A_{ik}) be given, and suppose the product P of all diagonal elements A_{ii} converges absolutely (equivalently, suppose $\sum |A_{ii} - 1|$ converges). Form a family of new products P' by permuting in P the second

⁶Von Koch, "Sur la convergence des déterminants d'ordre infini," *Bihang till K. Svenska Vetenskaps-Akademiens Handlingar*, vol. XXII (1896), no. 4, pp. 1–31.

indices in every possible way, assigning to each resulting product the sign + or – according as the number of transpositions required to pass from the initial product P to the product in question is even or odd. If the series Δ formed from all these products converges absolutely even when every A_{ii} is replaced by $1 + |A_{ii} - 1|$, we agree to regard Δ as the determinant of the A_{ik} and to say that the determinant *converges absolutely*.

27. Put $a_{ii} = A_{ii} - 1$ and $a_{ik} = A_{ik}$ for $i \neq k$. Expanding P, P' in products of the quantities a , von Koch's hypothesis plainly amounts to absolute convergence of the sum of all these products. Since the terms of an absolutely convergent sum may be arranged arbitrarily, Δ admits the expansions

$$\Delta_1 + (\Delta_2 - \Delta_1) + (\Delta_3 - \Delta_2) + \cdots,$$

and

$$1 + \sum_{i=1}^{\infty} a_{ii} + \sum_{i,j=1}^{\infty} \begin{vmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj} \end{vmatrix} + \sum_{i,j,k=1}^{\infty} \begin{vmatrix} a_{ii} & a_{ij} & a_{ik} \\ a_{ji} & a_{jj} & a_{jk} \\ a_{ki} & a_{kj} & a_{kk} \end{vmatrix} + \cdots.$$

Furthermore, if Δ converges absolutely, so do its principal minors

$$\begin{pmatrix} i_1, \dots, i_r \\ i_1, \dots, i_r \end{pmatrix},$$

for all products of the quantities a composing these minors also enter the expansion of Δ .

These principal minors cannot all vanish. Indeed, as $m \rightarrow \infty$, the sum of the products of a composing $\begin{pmatrix} 1, \dots, m \\ 1, \dots, m \end{pmatrix}$ tends to zero; hence that minor tends to 1 and is nonzero for all sufficiently large m .

For nonprincipal minors, it should be observed that absolute convergence of Δ does not always imply absolute convergence of its minors. But if none of the quantities a_{ik} ($i \neq k$) vanishes, absolute convergence of every minor follows at once from that of Δ itself.

Suppose in particular that Δ and, for a fixed index k , the minors $\begin{pmatrix} i \\ k \end{pmatrix}$ converge absolutely. By suitably arranging the terms one then obtains Laplace's rule

$$\Delta = \begin{pmatrix} k \\ k \end{pmatrix} + \sum_{i=1}^{\infty} a_{ik} \begin{pmatrix} i \\ k \end{pmatrix}.$$

These results make it easy to see that the determinant method applies to infinite systems of linear equations whenever the determinants and minors entering the calculation converge absolutely.

28. Von Koch gave a necessary and sufficient condition for absolute convergence of Δ . Consider the cyclic products of the quantities a_{ik} ; by a cyclic product of order r we mean any product of the form

$$a_{i_1 i_2} a_{i_2 i_3} \cdots a_{i_{r-1} i_r} a_{i_r i_1},$$

where $i_1, \dots, i_r$ are distinct. By a cyclic product of first order we mean a quantity a_{ii} . Since every cyclic product occurs in the expansion of Δ , absolute convergence of the series formed from all cyclic products is necessary for absolute convergence of Δ . This necessary condition is also sufficient. Indeed, form the infinite product $\prod(1 + |p|)$ over all cyclic products p . Its expansion contains in absolute value every term in the expansion of Δ . If $\sum |p|$ converges, then $\prod(1 + |p|)$ converges also, and consequently Δ converges absolutely.

Theorem. *The infinite determinant Δ converges absolutely if and only if the series formed from the cyclic products of the quantities a_{ik} converges absolutely.*

29. It is almost evident that normal determinants converge absolutely, as do the determinants obtained from them by replacing the elements of one column by quantities bounded as a whole. For normal determinants the infinite product $\prod_{i,k}(1 + |a_{ik}|)$ converges, and its expansion contains in absolute value all cyclic products. For determinants of the second type, a corresponding majorant is obtained by adjoining the factor $1 + C$ and suppressing the factors corresponding to the index k . Their minors belong to the same type and therefore also converge absolutely.

In seeking more general rules, von Koch constructed a succession of increasingly precise criteria for absolute convergence of Δ and all its minors. We shall give only one of the simplest, which is important for applications to integral equations.⁷

Theorem. *For Δ and all its minors to converge absolutely, it is sufficient that the two series*

$$\sum_{i=1}^{\infty} |a_{ii}|, \quad \sum_{i,k=1}^{\infty} |a_{ik}|^2$$

converge absolutely.

Proof. The minors belong to the same type as Δ , so it suffices to prove absolute convergence of Δ . By [the theorem just established](#), it is enough to prove convergence

⁷Von Koch, "Sur la convergence des déterminants infinis," *Rendiconti del Circolo matematico di Palermo*, vol. XXVIII (1909), pp. 255–266.

of the sum of the moduli of the cyclic products. Those of first order have been covered explicitly by the hypothesis; below we consider only orders greater than 1.

Following von Koch's proof, define σ by the following formula.^c

$$\sigma = \left(\sum_{i \neq k} |a_{ik}|^2 \right)^{1/2}.$$

Denote by $|i_1, i_2, \dots, i_r|$ the absolute value of the cyclic product $a_{i_1 i_2} a_{i_2 i_3} \cdots a_{i_r i_1}$, and by $|i_1, i_2, \dots, i_r; i_{r+1}|$ that of $a_{i_1 i_2} a_{i_2 i_3} \cdots a_{i_r i_{r+1}}$. The indices are required to be distinct; whenever this condition fails, both symbols are defined to be zero.

We shall use the Lagrange–Cauchy inequality⁸

$$\left| \sum_i a_i b_i \right|^2 \leq \left(\sum_i |a_i b_i| \right)^2 \leq \sum_i |a_i|^2 \sum_i |b_i|^2, \quad (15)$$

valid for arbitrary numbers. It follows from Lagrange's identity

$$\sum_i |a_i|^2 \sum_i |b_i|^2 = \left(\sum_i |a_i b_i| \right)^2 + \sum_{i < k} (|a_i b_k| - |a_k b_i|)^2.$$

The sums may contain infinitely many terms, provided the two series on the right of (15) converge; absolute convergence of the other series then follows immediately.

First suppose $\sigma < 1$. From (15),

$$\left(\sum_j |i, j; k| \right)^2 \leq \sum_j |i, j|^2 \sum_j |j, k|^2.$$

For $i = k$ this gives

$$\sum_{i,j} |i, j| \leq \sigma^2,$$

while for arbitrary i ,

$$\sum_k \left(\sum_j |i, j; k| \right)^2 \leq \sigma^2 \sum_j |i, j|^2.$$

^cTranslator's note: The French original prints σ^2 on the left. The estimates that follow require $\sigma = (\sum_{i \neq k} |a_{ik}|^2)^{1/2}$, equivalently $\sigma^2 = \sum_{i \neq k} |a_{ik}|^2$.

⁸Cauchy, *Cours d'Analyse de l'École royale Polytechnique*, Paris, 1824, Note II; *Oeuvres*, 2nd series, vol. III.

Consequently the inequalities

$$\sum_{i_1, \dots, i_n} |i_1, i_2, \dots, i_n| \leq \sigma^n, \quad (16)$$

and

$$\sum_j \left(\sum_{i_2, \dots, i_n} |i_1, i_2, \dots, i_n; j| \right)^2 \leq \sigma^{2n-2} \sum_j |i_1, j|^2 \quad (17)$$

hold for $n = 2$. Suppose they hold for a given n . Then

$$\begin{aligned} \sum_{i_1, \dots, i_{n+1}} |i_1, \dots, i_{n+1}| &= \sum_{i_1, i_{n+1}} \left(|i_{n+1}, i_1| \sum_{i_2, \dots, i_n} |i_1, \dots, i_n; i_{n+1}| \right) \\ &\leq \sum_{i_1} \left[\sum_{i_{n+1}} |i_{n+1}, i_1|^2 \sum_{i_{n+1}} \left(\sum_{i_2, \dots, i_n} |i_1, \dots, i_n; i_{n+1}| \right)^2 \right]^{1/2} \\ &\leq \left(\sum_{i_1, i_{n+1}} |i_{n+1}, i_1|^2 \sigma^{2n-2} \sum_{i_1, i_{n+1}} |i_1, i_{n+1}|^2 \right)^{1/2} \\ &\leq \sigma^{n+1}. \end{aligned}$$

Similarly,

$$\begin{aligned} &\sum_j \left(\sum_{i_2, \dots, i_{n+1}} |i_1, \dots, i_{n+1}; j| \right)^2 \\ &= \sum_j \left[\sum_{i_2} \left(|i_1, i_2| \sum_{i_3, \dots, i_{n+1}} |i_2, \dots, i_{n+1}; j| \right) \right]^2 \\ &\leq \sum_{i_2} |i_1, i_2|^2 \sum_{j, i_2} \left(\sum_{i_3, \dots, i_{n+1}} |i_2, \dots, i_{n+1}; j| \right)^2 \\ &\leq \sum_{i_2} |i_1, i_2|^2 \sigma^{2n-2} \sum_{i_2, j} |i_2, j|^2 \\ &= \sigma^{2n} \sum_k |i_1, k|^2. \end{aligned}$$

Thus, if (16) and (17) hold for n , they hold for $n + 1$; since they hold for $n = 2$, they hold for all n .

By (16), the sum of the moduli of all cyclic products of order greater than 1 is bounded by the convergent series

$$\sigma^2 + \sigma^3 + \cdots = \frac{\sigma^2}{1 - \sigma};$$

hence Δ converges absolutely.

We assumed $\sigma < 1$. The general case reduces to this special one. When $\sum_{i,k} |a_{ik}|^2$ converges, choose m so that

$$\sum_{i=m+1}^{\infty} \sum_{k=1}^{\infty} |a_{ik}|^2 < \frac{1}{2},$$

and then choose a sufficiently small positive t so that⁹

$$t^2 \sum_{i=1}^m \sum_{k=1}^{\infty} |a_{ik}|^2 < \frac{1}{2}.$$

Multiply by t the elements of the first m rows of Δ . It follows immediately from the definition in no. 26 that Δ converges absolutely if and only if the modified determinant does. For the latter $\sigma < 1$, so it converges absolutely; therefore Δ also converges absolutely. $\square$

30. The preceding considerations show that the results obtained for systems (10) and (12) may be extended by requiring of the unknowns x_k and the data a_{ik}, c_i that the series

$$\sum_k |x_k|^2, \quad \sum_i |a_{ii}|, \quad \sum_{i,k} |a_{ik}|^2, \quad \sum_i |c_i|^2$$

converge. The most important application of such systems is to integral equations. We shall discuss it later and shall see that all the present conditions arise quite naturally except convergence of $\sum |a_{ii}|$. This last condition can be removed by multiplying the equations of the system by suitable factors.

Indeed, suppose $\sum_i |c_i|^2$ and $\sum_{i,k} |a_{ik}|^2$, and hence in particular $\sum_i |a_{ii}|^2$, converge. Applying the inequality

$$|e^{-a}(1+a) - 1| = \left| -\frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{8} + \cdots \right| \leq \frac{|a|^2}{2} e^{|a|},$$

⁹Compare, in addition to von Koch's memoir, the Hungarian thesis of Szász, *A végtelen determinánsok elméletéhez*, Budapest, 1911, where these systems and their determinants are studied independently of the general theory of absolutely convergent determinants.

and observing that $a_{ii} \rightarrow 0$, one immediately obtains convergence of

$$\sum_i |e^{-a_{ii}} c_i|^2, \quad \sum_{i,k} |e^{-a_{ii}} a_{ik}|^2, \quad \sum_i |e^{-a_{ii}} (1 + a_{ii}) - 1|.$$

Thus, if each equation is multiplied by the corresponding quantity $e^{-a_{ii}}$, the modified system is of the type already considered.

31. Finally, suppose the data a_{ik} are functions $a_{ik}(\lambda)$ of a parameter λ , holomorphic in a domain D , and that the conditions imposed above are satisfied uniformly with respect to λ . For example, for normal determinants we assume that $\sum_{i,k} |a_{ik}(\lambda)|$ converges uniformly. The expansions given for Δ then converge uniformly, and the function $\Delta(\lambda)$ so defined is holomorphic in λ .

When λ is not a zero of $\Delta(\lambda)$, the system formed with the $a_{ik}(\lambda)$ has the well-determined solution

$$x_k(\lambda) = \frac{\Delta^{(k)}(\lambda)}{\Delta(\lambda)}.$$

As a function of λ , $x_k(\lambda)$ is meromorphic in the interior of the domain, and its poles are zeros of $\Delta(\lambda)$.

Expanding $\Delta(\lambda)$ as a series in products of the functions $a_{ik}(\lambda)$ gives an absolutely and uniformly convergent series; the general rules concerning series of analytic functions may therefore be applied to $\Delta(\lambda)$. In particular, successive derivatives with respect to λ may be calculated, and it is easy to specify conditions under which they have the same form as for finite-order determinants. Suppose, for example, that the series

$$\sum_{i,k} \left| \frac{da_{ik}(\lambda)}{d\lambda} \right|$$

converges uniformly in D . Then the expansion of $\Delta(\lambda)$ converges absolutely and uniformly there, and $d\Delta(\lambda)/d\lambda$ is obtained by termwise differentiation. Since the preceding series also converges and the first-order minors of $\Delta(\lambda)$ remain bounded as a whole, the series

$$\sum_{i,k} \binom{i}{k} \frac{da_{ik}}{d\lambda} \quad (18)$$

converges absolutely. The minors too may be expanded in products of the functions $a_{ik}(\lambda)$; even after every term is replaced by its absolute value, the resulting minors remain bounded as a whole. Thus, on expanding (18) in products of $a_{ik}(\lambda)$ and $da_{ik}(\lambda)/d\lambda$, the resulting series converges absolutely. Its terms may therefore be rearranged, in particular so as to give the series obtained by differentiating the

expansion of $\Delta(\lambda)$ term by term. Consequently, series (18) represents $d\Delta(\lambda)/d\lambda$. Finally, if

$$A_{ik}(\lambda) = \begin{cases} 1 + a_{ik}(\lambda), & i = k, \\ a_{ik}(\lambda), & i \neq k, \end{cases}$$

then $dA_{ik}(\lambda)/d\lambda = da_{ik}(\lambda)/d\lambda$. Replacing the latter derivatives by the former in (18) gives the customary formula for $d\Delta/d\lambda$.

Chapter III.

Essay Toward a General Theory

Introduction

32. To apply the classical method of determinants to infinite systems, it was necessary to impose more or less restrictive conditions on the data; and it must be admitted that these restrictions were required by the method, not by the problem. In what follows we shall adopt a much more general point of view, due in principle to E. Schmidt.¹ We shall begin by specifying the nature of the admissible solutions (x_k); as for the data, our sole hypothesis will be that, for every admissible system (x_k), the series occurring on the left-hand sides of the equations must converge. The principal question will be the *existence of solutions*; only secondarily shall we be concerned with the apparatus that produces them.

The most important case from the standpoint of applications is that in which one requires $\sum_k |x_k|^2$ to converge. To treat it by the method of determinants, we had to suppose that the double series $\sum_{i,k} |a_{ik}|^2$ and the series $\sum_i |c_i|^2$ converge. As we shall see, Schmidt's theory assumes only the convergence of the singly indexed series $\sum_k |a_{ik}|^2$. An intermediate theory was based by Hilbert on the study of quadratic forms and bilinear forms in infinitely many variables.² It is much more effective than the method of determinants, but less general than Schmidt's. As regards historical order, it should be observed that Hilbert's theory predates Schmidt's; it also predates the study of determinants for which $\sum_{i,k} |a_{ik}|^2$ converges, but it is later than the general theory of infinite and absolutely convergent determinants.

Chapters IV and V are devoted to Hilbert's theory. In the present chapter we shall set forth Schmidt's theory in a slightly generalized form.

The Fundamental Inequalities

33. We shall have occasion to start from the inequality

$$\left| \sum_{k=1}^n a_k b_k \right| \leq \left(\sum_{k=1}^n |a_k|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \left(\sum_{k=1}^n |b_k|^p \right)^{\frac{1}{p}} \quad (p > 1), \quad (1)$$

which concerns arbitrary quantities a_k, b_k , real or complex. Already established and used by Cauchy for $p = 2$,³ it was extended by Hölder to all $p > 1$.⁴

It is enough to prove inequality (1) for positive quantities a_k, b_k ; it will then hold, *a fortiori*, for arbitrary a and b . We may also suppose the a 's and b 's strictly positive, regarding the cases in which one or another of these quantities vanishes as limiting cases. Finally, we may suppose $n = 2$, for once the inequality has been proved in this particular case, it extends to every n by induction. It therefore remains to prove the inequality

$$a_1 b_1 + a_2 b_2 - \left(a_1^{\frac{p}{p-1}} + a_2^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} (b_1^p + b_2^p)^{\frac{1}{p}} \leq 0, \quad (2)$$

the quantities a_1, b_1, a_2, b_2 being supposed strictly positive.

The proof is readily carried out by the usual methods of differential calculus. Keeping a_1, a_2, b_1 fixed, let b_2 vary. The derivative with respect to b_2 of the expression on the left vanishes only when

$$b_2 = \left(\frac{a_2}{a_1} \right)^{\frac{1}{p-1}} b_1; \quad (3)$$

it is positive for every smaller value of b_2 and negative for every larger value. Hence the indicated value of b_2 makes our expression a maximum; substitution shows that this maximum is zero. Inequality (2) is therefore true; moreover, equality holds only in case (3).

For positive quantities a_k, b_k , Jensen has given a very interesting geometric interpretation of inequality (1). He considers the curve $y = x^p$ ($x > 0$). This curve is convex, that is, its chords lie above it. Let $P_1, \dots, P_n$ be the points of the curve whose abscissae are

$$a_1^{\frac{1}{1-p}} b_1, \dots, a_n^{\frac{1}{1-p}} b_n.$$

³Cf. no. 29.

⁴Hölder, "Ueber einen Mittelwertsatz," *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen* (1889), pp. 38–47.

Assign to these points the positive masses

$$a_1^{\frac{p}{p-1}}, \dots, a_n^{\frac{p}{p-1}}.$$

Then inequality (1) expresses the fact that the center of gravity of the system lies above the curve; equality can hold only when the points P_k coincide.⁵

Inequality (1) extends immediately to infinite series. Indeed, suppose that the two series

$$A = \sum |a_k|^{\frac{p}{p-1}}, \quad B = \sum |b_k|^p$$

converge. Then, by (1), the partial sums of the series $\sum |a_k b_k|$ do not exceed the bound $A^{(p-1)/p} B^{1/p}$. Consequently, the series $\sum a_k b_k$ converges absolutely, and

$$\left| \sum_{k=1}^{\infty} a_k b_k \right| \leq \left(\sum_{k=1}^{\infty} |a_k|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \left(\sum_{k=1}^{\infty} |b_k|^p \right)^{\frac{1}{p}} \quad (p > 1). \quad (4)$$

34. We shall also use the inequality

$$\left(\sum_{k=1}^{\infty} |a_k + b_k|^p \right)^{\frac{1}{p}} \leq \left(\sum_{k=1}^{\infty} |a_k|^p \right)^{\frac{1}{p}} + \left(\sum_{k=1}^{\infty} |b_k|^p \right)^{\frac{1}{p}} \quad (p > 1). \quad (5)$$

It is obtained by an analysis entirely analogous to the preceding one, but it also follows immediately from inequality (4). We shall merely present the case of four positive quantities a_1, a_2, b_1, b_2 , since one passes from this particular case to the general case by reasoning exactly as above.⁶

Applying (2), we write

$$\begin{aligned} & (a_1 + b_1)^p + (a_2 + b_2)^p \\ &= (a_1 + b_1)^{p-1} a_1 + (a_2 + b_2)^{p-1} a_2 + (a_1 + b_1)^{p-1} b_1 + (a_2 + b_2)^{p-1} b_2 \\ &\leq \left[(a_1 + b_1)^p + (a_2 + b_2)^p \right]^{\frac{p-1}{p}} \left[(a_1^p + a_2^p)^{\frac{1}{p}} + (b_1^p + b_2^p)^{\frac{1}{p}} \right]; \end{aligned} \quad (6)$$

⁵Jensen, "Sur les fonctions convexes et les inégalités entre les valeurs moyennes," *Acta Mathematica*, vol. XXX (1906), pp. 175–193.

⁶For a finite number of terms, inequality (5) was established by Minkowski: *Diophantische Approximationen*, 1907, p. 95. That work treats the important theory which its author calls the geometry of numbers. In the order of ideas of that theory, inequality (5) expresses the convexity of the n -dimensional domain $\sum_{k=1}^n |x_k|^p \leq 1$. Notice that, in the arguments to follow, inequality (5) could in most cases be replaced by the nearly evident inequality

$$\sum_{k=1}^{\infty} |a_k + b_k|^p \leq 2^p \sum_{k=1}^{\infty} |a_k|^p + 2^p \sum_{k=1}^{\infty} |b_k|^p.$$

equality is possible only if

$$a_2 = \frac{a_2 + b_2}{a_1 + b_1} a_1, \quad b_2 = \frac{a_2 + b_2}{a_1 + b_1} b_1,$$

that is, only if $a_1 b_2 = a_2 b_1$.

Dividing by

$$\left[(a_1 + b_1)^p + (a_2 + b_2)^p \right]^{\frac{p-1}{p}},$$

we obtain the inequality to be proved:

$$\left[(a_1 + b_1)^p + (a_2 + b_2)^p \right]^{\frac{1}{p}} \leq (a_1^p + a_2^p)^{\frac{1}{p}} + (b_1^p + b_2^p)^{\frac{1}{p}};$$

equality holds only in the case just described.

Here is a second form of our inequality, obtained by replacing a_k in it by $a_k - b_k$:

$$\left(\sum_{k=1}^{\infty} |a_k - b_k|^p \right)^{\frac{1}{p}} \geq \left(\sum_{k=1}^{\infty} |a_k|^p \right)^{\frac{1}{p}} - \left(\sum_{k=1}^{\infty} |b_k|^p \right)^{\frac{1}{p}}. \quad (7)$$

Let us further specify the conditions under which equality holds in (5). It is necessary and sufficient that the b 's be proportional to the a 's,

$$a_1 : b_1 = a_2 : b_2 = \cdots,$$

and that these ratios be positive.

These conditions are plainly sufficient. Let us show that they are also necessary. When the second condition is not fulfilled, one can increase the values of the terms $|a_k + b_k|^p$ without changing the absolute values of the a 's and b 's. Thus this condition must be fulfilled; and when it is, we may suppose without loss of generality that the a 's and b 's are positive. But in that case equality can hold only when the b 's are proportional to the a 's. Indeed, suppose, to fix ideas, that $a_1 : b_1 \neq a_2 : b_2$, that is, $a_1 b_2 \neq a_2 b_1$. We have just seen that in this case the strict inequality sign applies in (6); hence one can increase

$$(a_1 + b_1)^p + (a_2 + b_2)^p$$

without changing either $a_1^p + a_2^p$ or $b_1^p + b_2^p$. The left-hand side of (5) will thus have been increased without changing the right-hand side; consequently equality is excluded in the case under consideration.

The Problem. Landau's Theorem

35. Consider the system formed by a finite or countably infinite number of equations

$$\sum_{k=1}^{\infty} a_{ik} x_k = c_i \quad (i = 1, 2, \dots). \quad (8)$$

Given a number $p > 1$, chosen arbitrarily once and for all, we propose to determine a solution (x_k) of the system in such a way that the series

$$\sum_{k=1}^{\infty} |x_k|^p \quad (9)$$

converges.

As for the data, we make only one hypothesis. Under this hypothesis the equations (8) must have a meaning. But before carrying out the solution, we know nothing about the quantities x_k . We are therefore led to suppose that the left-hand sides of (8) converge for every system (x_k) for which the series (9) converges. This is equivalent to assuming that, for every i , the sums

$$\sum_{k=1}^{\infty} |a_{ik}|^{\frac{p}{p-1}}$$

converge. Indeed, Hellinger and Toeplitz proved for $p = 2$,⁷ and Landau for arbitrary $p > 1$,⁸ that the series

$$\sum_{k=1}^{\infty} a_k x_k \quad (10)$$

cannot converge for every system (x_k) for which the series (9) converges unless

$$\sum_{k=1}^{\infty} |a_k|^{\frac{p}{p-1}} \quad (11)$$

converges. Conversely, when this last condition is fulfilled, inequality (1) establishes the absolute convergence of the series (10).

⁷Hellinger and Toeplitz, "Grundlagen für eine Theorie der unendlichen Matrizen," *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen* (1906), pp. 351–355.

⁸Landau, "Ueber einen Konvergenzsatz," *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen* (1907), pp. 25–27.

Landau's Theorem. *If the series (10) converges for every system (x_k) for which the series (9) converges, then the series (11) converges.*

Proof. Suppose that the latter series diverges. We shall define a system (x_k) for which (9) converges and (10) diverges. Put

$$s_0 = 0, \quad s_n = \sum_{k=1}^n |a_k|^{\frac{p}{p-1}};$$

then $s_n \rightarrow \infty$. Divide the sequence of indices $0, 1, 2, \dots$ into groups

$$0; \quad 1, 2, \dots, n_1; \quad n_1 + 1, \dots, n_2; \quad \dots,$$

in such a way that

$$s_{n_v} - s_{n_{v-1}} \geq 2^{\frac{v}{p-1}}.$$

For an index k belonging to the group ending with n_v , put

$$x_k = \frac{|a_k|^{\frac{1}{p-1}} \operatorname{sgn}^* a_k}{s_{n_v} - s_{n_{v-1}}}.$$

It follows that

$$\sum_{k=1}^{n_v} a_k x_k = v,$$

and series (10) diverges. On the other hand,

$$\sum_{k=1}^{n_v} |x_k|^p = \sum_{\mu=1}^v (s_{n_\mu} - s_{n_{\mu-1}})^{1-p} \leq \sum_{\mu=1}^v \frac{1}{2^\mu};$$

therefore series (9) converges. □

A Necessary Condition

36. Suppose that system (8) admits a solution such that

$$\sum_{k=1}^{\infty} |x_k|^p \leq M^p. \tag{12}$$

⁹For the notation sgn^* , cf. the remark in [no. 21](#).

Let $\mu_1, \dots, \mu_n$ be arbitrary numbers, real or complex. The values (x_k) also satisfy the equation

$$\sum_{k=1}^{\infty} \left(\sum_{i=1}^n \mu_i a_{ik} \right) x_k = \sum_{i=1}^n \mu_i c_i,$$

which is simply a linear combination of the first n equations of (8).

Applying inequality (4), we obtain

$$\begin{aligned} \left| \sum_{i=1}^n \mu_i c_i \right| &= \left| \sum_{k=1}^{\infty} \left(\sum_{i=1}^n \mu_i a_{ik} \right) x_k \right| \\ &\leq \left(\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \left(\sum_{k=1}^{\infty} |x_k|^p \right)^{\frac{1}{p}}. \end{aligned} \quad (13)$$

By (12), it follows that

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq M \left(\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}}. \quad (14)$$

Thus we have established a necessary condition for system (8) to admit a solution satisfying (12): inequality (14) must hold for every n and all real or complex numbers μ_i . (When the number of equations (8) is finite, n may be fixed and taken equal to the number of equations.)

We shall see that this condition is also sufficient.

The Condition Is Also Sufficient: The Case of Finitely Many Equations

37. First consider the particular case of finitely many equations

$$\sum_{k=1}^{\infty} a_{ik} x_k = c_i \quad (i = 1, 2, \dots, n). \quad (15)$$

Suppose the condition is fulfilled. Put

$$A_k(\mu_1, \dots, \mu_n) = \sum_{i=1}^n \mu_i a_{ik}, \quad A(\mu_1, \dots, \mu_n) = \sum_{k=1}^{\infty} |A_k(\mu_1, \dots, \mu_n)|^{\frac{p}{p-1}},$$

and

$$C(\mu_1, \dots, \mu_n) = \left| \sum_{i=1}^n \mu_i c_i \right|^{\frac{p}{p-1}}.$$

The function $C(\mu_1, \dots, \mu_n)$ is continuous in the n variables $\mu_1, \dots, \mu_n$. It is also continuous as a function of the $2n$ real variables

$$\mu'_1, \mu''_1, \dots, \mu'_n, \mu''_n \quad (\mu_i = \mu'_i + \mu''_i \sqrt{-1}).$$

Moreover, with respect to these $2n$ variables it has continuous first derivatives. To simplify the calculation, we shall consider only the combinations

$$\frac{\partial C}{\partial \mu'_i} - \sqrt{-1} \frac{\partial C}{\partial \mu''_i}$$

of these derivatives. We have

$$\frac{\partial C}{\partial \mu'_i} - \sqrt{-1} \frac{\partial C}{\partial \mu''_i} = \frac{p}{p-1} c_i C^{\frac{1}{p}} \operatorname{sgn}^* \left(\sum_{j=1}^n \mu_j c_j \right). \quad (16)$$

Similarly,

$$\frac{\partial |A_k|^{\frac{p}{p-1}}}{\partial \mu'_i} - \sqrt{-1} \frac{\partial |A_k|^{\frac{p}{p-1}}}{\partial \mu''_i} = \frac{p}{p-1} a_{ik} |A_k|^{\frac{1}{p-1}} \operatorname{sgn}^* A_k. \quad (17)$$

As for the function $A(\mu_1, \dots, \mu_n)$, first observe that the series defining it converges for every system of values $\mu_1, \dots, \mu_n$. This follows by successively applying inequality (5) to the sequences $(\mu_1 a_{1k}), \dots, (\mu_n a_{nk})$, with the exponent p there replaced by $p/(p-1)$, which is permissible since $p/(p-1) > 1$. The same inequality also proves that the series defining $A(\mu_1, \dots, \mu_n)$ converges uniformly in every bounded domain of the μ 's; hence $A(\mu_1, \dots, \mu_n)$ is a continuous function of the variables μ'_i, μ''_i .

Differentiate the series defining $A(\mu_1, \dots, \mu_n)$ term by term with respect to μ'_i (or μ''_i). The absolute value of the k th term of the resulting series does not exceed the right-hand side of (17). Consequently,

$$\begin{aligned} \frac{p}{p-1} \sum_{k=1}^{\infty} |a_{ik}| |A_k|^{\frac{1}{p-1}} &\leq \frac{p}{p-1} \left(\sum_{k=1}^{\infty} |a_{ik}|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \left(\sum_{k=1}^{\infty} |A_k|^{\frac{p}{p-1}} \right)^{\frac{1}{p}} \\ &= \frac{p}{p-1} A(\mu_1, \dots, \mu_n)^{\frac{1}{p}} \left(\sum_{k=1}^{\infty} |a_{ik}|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \end{aligned}$$

is a majorant for the differentiated series. Since the majorant converges uniformly in every bounded domain of the μ 's, the differentiated series does likewise. It follows from a well-known theorem on differentiation of series that the function $A(\mu_1, \dots, \mu_n)$ has continuous partial derivatives obtained by differentiating term by term. Hence

$$\frac{\partial A}{\partial \mu'_i} - \sqrt{-1} \frac{\partial A}{\partial \mu''_i} = \frac{p}{p-1} \sum_{k=1}^{\infty} a_{ik} |A_k|^{\frac{1}{p-1}} \operatorname{sgn}^* A_k. \quad (18)$$

38. These preliminaries established, suppose for the moment that the left-hand sides of equations (15) are independent. This hypothesis may be formulated by requiring that $A(\mu_1, \dots, \mu_n)$ cannot vanish unless all the μ 's vanish. The restriction is not essential; we shall remove it at the end of the argument. For the moment it allows us to conclude that, when A is bounded, the quantities μ remain bounded as well. Indeed, otherwise there would be an infinite sequence of systems (μ_i) such that, for at least one index i , the values (μ_i) would grow beyond every bound, while the function A remained bounded. The homogeneity of A would then yield a sequence of systems (μ_i) for each of which the largest value $|\mu_i|$ was exactly 1, while the corresponding values of A tended to zero. By Weierstrass's theorem, such a sequence contains a subsequence converging to a definite system $(\mu_i^{(0)})$. The values $\mu_i^{(0)}$ do not all vanish, since the largest $|\mu_i^{(0)}|$ is exactly 1. On the other hand, continuity of A would imply

$$A(\mu_1^{(0)}, \dots, \mu_n^{(0)}) = 0,$$

contrary to the hypothesis.

The functions A and C are continuous in the μ 's, and when A is bounded the μ 's remain bounded; hence C remains bounded as well. Consequently, when C is allowed to vary under the condition $A = 1$, it attains its maximum for certain values $\mu_1, \dots, \mu_n$. The classical method of differential calculus gives, for these values of the μ 's, the equations

$$\left\{ \begin{aligned} & c_i C(\mu_1, \dots, \mu_n)^{\frac{1}{p}} \operatorname{sgn}^* \left(\sum_{j=1}^n \mu_j c_j \right) \\ & = \lambda \sum_{k=1}^{\infty} a_{ik} |A_k(\mu_1, \dots, \mu_n)|^{\frac{1}{p-1}} \operatorname{sgn}^* A_k(\mu_1, \dots, \mu_n) \quad (i = 1, 2, \dots, n), \end{aligned} \right. \quad (19)$$

and

$$A(\mu_1, \dots, \mu_n) = 1. \quad (20)$$

Multiplying equations (19) by μ_i and adding, we obtain

$$\lambda = C(\mu_1, \dots, \mu_n).$$

Consequently, for the values of the μ 's under consideration,

$$\left(\sum_{j=1}^n \mu_j c_j \right) \sum_{k=1}^{\infty} a_{ik} |A_k(\mu_1, \dots, \mu_n)|^{\frac{1}{p-1}} \operatorname{sgn}^* A_k(\mu_1, \dots, \mu_n) = c_i \quad (i = 1, 2, \dots, n).$$

But this is precisely the solution of system (15) which we have just obtained. Indeed, with $\mu_1, \dots, \mu_n$ denoting the extremal values in question, put

$$x_k^{(n)} = |A_k(\mu_1, \dots, \mu_n)|^{\frac{1}{p-1}} \operatorname{sgn}^* A_k(\mu_1, \dots, \mu_n) \sum_{i=1}^n \mu_i c_i \quad (k = 1, 2, \dots). \quad (21)$$

The quantities $x_k^{(n)}$ so defined satisfy equations (15). Moreover, it follows from (14), (20), and (21) that

$$\sum_{k=1}^{\infty} |x_k^{(n)}|^p = \left| \sum_{i=1}^n \mu_i c_i \right|^p \leq M^p, \quad (22)$$

that is, under the stated conditions, system (15) admits a solution satisfying (12).

Inequality (22) may be replaced by a more precise relation. Let $M^{(n)}$ be the least of the numbers M satisfying inequality (14) for every choice of $\mu_1, \dots, \mu_n$. Then $[M^{(n)}]^{p/(p-1)}$ is the maximum value of $C(\mu_1, \dots, \mu_n)$ under condition (20). This maximum is attained for the values of the μ 's which furnished the solution $(x_k^{(n)})$. Hence

$$\sum_{k=1}^{\infty} |x_k^{(n)}|^p = \left| \sum_{i=1}^n \mu_i c_i \right|^p = [M^{(n)}]^p. \quad (23)$$

On the other hand, by inequality (13), every solution (x_k) of system (15) satisfies

$$\sum_{k=1}^{\infty} |x_k|^p \geq \left[\frac{C(\mu_1, \dots, \mu_n)}{A(\mu_1, \dots, \mu_n)} \right]^{p-1} = [M^{(n)}]^p.$$

Thus the solution found, $(x_k^{(n)})$, has a second extremal property: among all solutions of system (15), it is the one for which the sum $\sum |x_k|^p$ is as small as possible.

I say that $(x_k^{(n)})$ is the only solution having the property just observed. Indeed, let (x_k) be another such solution. Inequality (5) gives

$$\sum_{k=1}^{\infty} \left| \frac{x_k^{(n)} + x_k}{2} \right|^p \leq \left[\frac{1}{2} \left(\sum_{k=1}^{\infty} |x_k^{(n)}|^p \right)^{\frac{1}{p}} + \frac{1}{2} \left(\sum_{k=1}^{\infty} |x_k|^p \right)^{\frac{1}{p}} \right]^p = [M^{(n)}]^p.$$

Since $((x_k^{(n)} + x_k)/2)$ also satisfies system (15), equality must hold. In [no. 34](#), while discussing inequality (5), we also specified the conditions for equality; apply the criteria found there to the present case. We must have

$$x_1^{(n)} : x_1 = x_2^{(n)} : x_2 = \cdots ,$$

and these ratios must be positive. But, on the other hand,

$$\sum_{k=1}^{\infty} |x_k^{(n)}|^p = \sum_{k=1}^{\infty} |x_k|^p.$$

Thus the ratio in question is 1, unless system (15) is homogeneous.^d The homogeneous case is evident: its extremal solution is $x_1 = x_2 = \cdots = 0$.

It remains to remove the restriction that the left-hand sides of equations (15) be independent. Inequality (14) assures us that, whenever a linear combination of the left-hand sides vanishes identically, the same combination of the right-hand sides also vanishes. We may therefore suppress certain equations so that the remaining system is equivalent to the original system and at the same time is of the type considered. It is clear that reducing the system in this way does not alter the minimum of the M 's.

39. In the foregoing, we connected the solution of system (15) with another problem: to maximize the expression C while the μ 's vary under the condition $A = 1$. I shall try in a few words to explain the order of ideas leading from the first problem to the second. Let us forget for a moment the preceding developments and suppose only that system (15) admits solutions for which $\sum |x_k|^p$ converges, and that among these solutions there is one which makes this sum a minimum; that is, suppose there is a system $(x_k^{(n)})$ which minimizes the function $\sum |x_k|^p$ of the variables x_k , the x 's varying in accordance with conditions (15). The classical method of differential calculus shows that this particular solution $x_k^{(n)}$ must have

^d*Translator's note:* The French original reads "unless the system is not homogeneous"; the argument and the following sentence require "unless the system is homogeneous."

the form (21), the values of the μ 's still remaining to be determined. Equations for the unknowns μ are obtained by substituting expressions (21) in equations (15).

The resulting equations are linear when $p = 2$; we shall return later to this particular case. But in the general case they are quite complicated. In that case one must be content to prove the *existence* of a solution; that will suffice to infer the existence of the minimum solution ($x_k^{(n)}$) of (15). This is what we did by following an indirect route, one suggested by inequality (13). Indeed, let $\mu_1^{(n)}, \dots, \mu_n^{(n)}$ be the values to be determined which serve to define the $x_k^{(n)}$. Substitution of the expressions for $x_k^{(n)}$ in (13) gives

$$\frac{C(\mu_1, \dots, \mu_n)}{A(\mu_1, \dots, \mu_n)} \leq \frac{C(\mu_1^{(n)}, \dots, \mu_n^{(n)})}{A(\mu_1^{(n)}, \dots, \mu_n^{(n)})},$$

whatever the values $\mu_1, \dots, \mu_n$. Since, on the other hand, by (20),^e

$$A(\mu_1^{(n)}, \dots, \mu_n^{(n)}) = 1,$$

the $\mu_i^{(n)}$ must solve the maximum problem from which we started.

Let us add that, when $c_1 = 1$ and the other c 's vanish, our method is approximately the one Schmidt used for $p = 2$ in the work cited in no. 32. In this case our constrained maximum problem is immediately transformed into an unconstrained minimum problem: minimize the expression

$$\left(\sum_{k=1}^{\infty} \left| a_{1k} - \sum_{i=2}^n \mu_i a_{ik} \right|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}}.$$

The minimum value of this expression permits an interesting geometric interpretation. It may be regarded in infinite-dimensional space as the distance from the point with coordinates a_{1k} ($k = 1, 2, \dots$) to the linear variety determined by the $n - 1$ points $(a_{2k}), \dots, (a_{nk})$, the distance between two points (b_k) and (c_k) being measured by

$$\left(\sum_{k=1}^{\infty} |b_k - c_k|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}}.$$

^e*Translator's note:* The French original refers here to equation (15); the asserted equality is equation (20).

Theorems Concerning Sequences of Systems (y_k)

40. Before passing to the general case, let us establish several theorems which we shall use.

Consider the infinite sequence of quantities $y_1^{(n)}, y_2^{(n)}, \dots$. We suppose that these quantities vary with n , but in such a way that constantly

$$\sum_{k=1}^{\infty} |y_k^{(n)}|^p \leq G^p,$$

where G denotes a positive number independent of n . Suppose further that, as $n \rightarrow \infty$, each $y_k^{(n)}$ tends to a definite value y_k^* . We shall then say that *the sequence of systems ($y_k^{(n)}$) tends to the system (y_k^*)*.

Let us prove that one also has

$$\sum_{k=1}^{\infty} |y_k^*|^p \leq G^p. \quad (24)$$

Indeed, for arbitrary m ,

$$\sum_{k=1}^m |y_k^*|^p = \lim_{n \rightarrow \infty} \sum_{k=1}^m |y_k^{(n)}|^p \leq G^p.$$

Since the partial sums of the positive-term series (24) remain at most G^p , the series converges and its sum is likewise at most G^p .

Now consider the series

$$\sum_{k=1}^{\infty} a_k y_k; \quad (25)$$

we have already seen that, when the series $\sum |a_k|^{p/(p-1)}$ and $\sum |y_k|^p$ converge, series (25) converges absolutely. Moreover, series (25) converges *uniformly* over the set of systems (y_k) such that

$$\sum_{k=1}^{\infty} |y_k|^p \leq G^p. \quad (26)$$

Indeed, inequality (4) gives, for every system satisfying (26),

$$\left| \sum_{k=m+1}^{\infty} a_k y_k \right| \leq G \left(\sum_{k=m+1}^{\infty} |a_k|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}}; \quad (27)$$

the right-hand side no longer depends on the y 's and tends to zero as $1/m$ tends to zero.

In particular, apply inequality (27) to the systems $(y_k^{(n)})$ and (y_k^*) just considered. We obtain, for arbitrary m ,

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \sum_{k=1}^{\infty} a_k (y_k^* - y_k^{(n)}) \right| &\leq \lim_{n \rightarrow \infty} \left| \sum_{k=1}^m a_k (y_k^* - y_k^{(n)}) \right| \\ &\quad + \lim_{n \rightarrow \infty} \left| \sum_{k=m+1}^{\infty} a_k y_k^{(n)} \right| + \left| \sum_{k=m+1}^{\infty} a_k y_k^* \right| \\ &\leq 0 + 2G \left(\sum_{k=m+1}^{\infty} |a_k|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}}. \end{aligned}$$

Since this holds for every m , the limit on the left is zero¹⁰ and

$$\sum_{k=1}^{\infty} a_k y_k^* = \lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} a_k y_k^{(n)}. \quad (28)$$

41. Besides inequality (24) and equality (28), which we shall use below, we shall also need a *selection principle*. For the sequences of systems $(y_k^{(n)})$ which we shall have to consider, it will allow us to infer the existence of subsequences tending to limiting systems.¹¹

Selection Principle. *Given an infinite sequence of systems $(y_k^{(n)})$ satisfying inequality (26), one can extract from it a subsequence of systems*

$$(y_k^{(n_1)}), (y_k^{(n_2)}), \dots$$

¹⁰This result is a special case of the following theorem, which is likewise very easy to prove: *If the sequence $(y_k^{(n)})$ tends to (y_k^*) as $n \rightarrow \infty$, and if, moreover, the quantities $a_k^{(n)}$ tend to limits a_k^* in such a way that*

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |a_k^* - a_k^{(n)}|^{\frac{p}{p-1}} = 0,$$

then

$$\sum_{k=1}^{\infty} a_k^* y_k^* = \lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} a_k^{(n)} y_k^{(n)}.$$

¹¹For the history of this principle and its role in analysis, see Fréchet, *Sur quelques points du Calcul fonctionnel*, thesis, Paris, 1906 (also printed in the *Rendiconti del Circolo Matematico di Palermo*, vol. XXII, 1906), Chapters IV–VII.

which tends to a system (y_k^*) .

Proof. Consider the sequence of quantities $y_1^{(n)}$ ($n = 1, 2, \dots$). Their absolute values remain at most G . Hence, by Weierstrass's theorem, the sequence has one or more limiting values. Choose one of them and call it y_1^* , and let $n'_1, n'_2, \dots$ be a sequence of indices such that^f

$$y_1^{(n'_1)}, y_1^{(n'_2)}, \dots$$

tends to y_1^* . Likewise, the sequence

$$y_2^{(n'_1)}, y_2^{(n'_2)}, \dots$$

has one or more limiting values. Let y_2^* be one of them, and let $n''_1, n''_2, \dots$ be a sequence of indices selected from the preceding sequence such that

$$y_2^{(n''_1)}, y_2^{(n''_2)}, \dots$$

tends to y_2^* . Continuing this procedure, we determine values $y_3^*, y_4^*, \dots$ and corresponding sequences $(n'''_i), (n^{iv}_i), \dots$, each selected from its predecessor. Now put

$$n_1 = n'_1, \quad n_2 = n''_2, \quad n_3 = n'''_3, \quad \dots$$

Except always for a finite number of terms, the sequence (n_i) so defined is contained in each of the sequences $(n'_i), (n''_i), \dots$. Consequently, for every k ,

$$y_k^* = \lim_{i \rightarrow \infty} y_k^{(n_i)},$$

as was to be proved. □

42. In certain cases our selection principle allows us to conclude that the sequence $(y_k^{(n)})$ itself already tends to a limiting system (y_k^*) . This always occurs when the system (y_k^*) is uniquely determined by the problem from which one started. Indeed, suppose that for some k , say $k = k_1$, one did not have

$$y_{k_1}^* = \lim_{n \rightarrow \infty} y_{k_1}^{(n)}.$$

Since the quantities $y_{k_1}^{(n)}$ are bounded as a whole, they would have a second limiting value

$$y_{k_1}^{**} \neq y_{k_1}^*, \tag{29}$$

^f*Translator's note:* The French text says to choose "the least" limiting value, although the quantities may be complex and hence are not ordered. Any limiting value suffices.

and there would be a sequence of indices $m_1, m_2, \dots$ such that

$$y_{k_1}^{**} = \lim_{i \rightarrow \infty} y_{k_1}^{(m_i)}.$$

But our selection principle also applies to the sequence

$$(y_k^{(m_1)}), (y_k^{(m_2)}), \dots;$$

applied to this sequence, it would yield a limiting system (y_k^{**}) , which by (29) would be distinct from (y_k^*) , contrary to the hypothesis.

43. So far, in considering sequences of systems $(y_k^{(n)})$ that tend term by term to a system (y_k^*) , we have made only one mildly restrictive hypothesis: that the sums

$$\sum_{k=1}^{\infty} |y_k^{(n)}|^p \quad (n = 1, 2, \dots) \quad (30)$$

remain bounded as a whole. Inequality (24) assured us that the sum

$$\sum_{k=1}^{\infty} |y_k^*|^p \quad (31)$$

could not exceed any limiting value of the sequence (30).

Now consider the case in which precisely

$$\sum_{k=1}^{\infty} |y_k^*|^p = \lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |y_k^{(n)}|^p. \quad (32)$$

We shall show that in this case one also has

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |y_k^* - y_k^{(n)}|^p = 0. \quad (33)$$

Let ε be an arbitrarily small positive quantity. Since series (31) converges, m may be chosen so that

$$\sum_{k=m+1}^{\infty} |y_k^*|^p = \lim_{n \rightarrow \infty} \sum_{k=m+1}^{\infty} |y_k^{(n)}|^p < \varepsilon^p.$$

Having chosen m in this way, inequality (5) gives

$$\lim_{n \rightarrow \infty} \sum_{k=m+1}^{\infty} |y_k^* - y_k^{(n)}|^p \leq \lim_{n \rightarrow \infty} \left[\left(\sum_{k=m+1}^{\infty} |y_k^*|^p \right)^{\frac{1}{p}} + \left(\sum_{k=m+1}^{\infty} |y_k^{(n)}|^p \right)^{\frac{1}{p}} \right]^p$$

$$< (2\varepsilon)^p.$$

On the other hand,

$$\lim_{n \rightarrow \infty} \sum_{k=1}^m |y_k^* - y_k^{(n)}|^p = 0,$$

since only finitely many terms are involved, each tending to zero. Consequently,

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |y_k^* - y_k^{(n)}|^p < (2\varepsilon)^p;$$

and since the left-hand side does not depend on the value of ε , it must be zero.¹²

The Case of Infinitely Many Equations

44. Having established the necessary preliminaries, let us now study the case in which system (8) consists of a countably infinite number of equations. Suppose condition (14) fulfilled, and let M^* be the least of the numbers M for which (14) holds. Then the condition is also satisfied by the first n equations of (8), and $M^{(n)} \leq M^*$. Let $(x_k^{(n)})$ be the extremal solution (no. 38) of these n equations. We

¹²Conversely, if equation (33) holds, it plainly entails the term-by-term convergence of the $y_k^{(n)}$ to the y_k^* ; it also entails relation (32), as follows immediately from inequality (7). Let us add that, for $p = 2$, this type of convergence (*strong convergence*) was introduced by Hilbert (loc. cit., 4th Communication, p. 177); it is also precisely the type used by Schmidt in his investigations. Let us state two further theorems concerning strong convergence; both follow readily from the preceding arguments. The first was established for $p = 2$ by Schmidt, and the second, for the same case, by Fréchet (*Comptes rendus*, June 24, 1907). Here is the first: *Given the sequence $(y_k^{(n)})$, in order that there exist a system (y_k^*) such that the systems $(y_k^{(n)})$ tend strongly to (y_k^*) , it is necessary and sufficient that*

$$\lim_{m \rightarrow \infty, n \rightarrow \infty} \sum_{k=1}^{\infty} |y_k^{(m)} - y_k^{(n)}|^p = 0.$$

The second theorem constitutes a kind of selection principle for strong convergence: *Given a sequence $(y_k^{(n)})$, in order that one may extract from it a subsequence which converges strongly, it is necessary and sufficient that the series*

$$\sum_{k=1}^{\infty} |y_k^{(n)}|^p$$

converge uniformly for all n .

have

$$\sum_{k=1}^{\infty} |x_k^{(n)}|^p = [M^{(n)}]^p \leq (M^*)^p. \quad (34)$$

Thus the sequence of systems $(x_k^{(n)})$ ($n = 1, 2, \dots$) contains a subsequence

$$(x_k^{(n_1)}), (x_k^{(n_2)}), \dots$$

tending to a system (x_k^*) . Applying formula (28) to this system, we see immediately that the values x_k^* satisfy each of equations (8). Moreover, the solution of (8) so defined is an extremal solution in the sense of no. 38, for inequality (24) gives

$$\sum_{k=1}^{\infty} |x_k^*|^p \leq (M^*)^p,$$

while inequality (13) gives, for every solution (x_k) of (8),

$$\sum_{k=1}^{\infty} |x_k|^p \geq (M^*)^p. \quad (35)$$

But there is more. System (8) has only one extremal solution. We have already proved this for the finite system (15);

The same reasoning applies in the general case. Now, (x_k^*) is such an extremal solution; and the same would be true of every other system obtained, in accordance with our principle of choice, from the sequence of systems $(x_k^{(n)})$. Consequently, by no. 42,

$$x_k^* = \lim_{n \rightarrow \infty} x_k^{(n)}. \quad (36)$$

But the nature of the convergence of the solutions $(x_k^{(n)})$ to the solution (x_k^*) can be specified much more precisely. It follows from (34), (35), and (36) that

$$\sum_{k=1}^{\infty} |x_k^*|^p = M^{*p} = \lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |x_k^{(n)}|^p;$$

hence, by no. 43,

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |x_k^* - x_k^{(n)}|^p = 0.$$

In summary, we may state the following theorem.

Theorem. *For the system of a finite or countably infinite number of equations*

$$\sum_{k=1}^{\infty} a_{ik} x_k = c_i \quad (i = 1, 2, \dots),$$

whose coefficients a_{ik} are such that the series

$$\sum_{k=1}^{\infty} |a_{ik}|^{p/(p-1)} \quad (i = 1, 2, \dots)$$

converge, to admit at least one solution (x_k) such that

$$\sum_{k=1}^{\infty} |x_k|^p \leq M^p,$$

it is necessary and sufficient that the inequality

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq M \left(\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right)^{(p-1)/p}$$

hold for every n and every choice of the numbers μ_i , real or complex.

In particular, if M denotes the least of the numbers for which the condition is fulfilled, there is only one solution possessing the required property. In the case of infinitely many equations, this extremal solution (x_k^) is related to the extremal solutions $(x_k^{(n)})$ of the partial systems (15) by*

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |x_k^* - x_k^{(n)}|^p = 0.$$

45. Let us now make a remark which may perhaps suggest to the reader another proof of the facts just established. Let (x_k^*) be the extremal solution of system (8), and adjoin to that system the equation $x_1 = x_1^*$; the modified system clearly has the same extremal solution. Applying formula (14) to this new system leads to the inequality

$$\left| x_1^* - \sum_{i=1}^n \mu_i c_i \right| \leq M^* \left(\left| 1 - \sum_{i=1}^n \mu_i a_{i1} \right|^{p/(p-1)} + \sum_{k=2}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right)^{(p-1)/p}.$$

This inequality says that the point x_1^* in the complex plane must lie inside, or on the circumference of, the circle whose centre is $\sum \mu_i c_i$ and whose radius is

given by the right-hand side of the inequality. Thus x_1^* belongs to every circle corresponding to the different possible choices of n and the μ_i ; and, since the extremal solution is unique, these circles have no other common point.

The same reasoning applies to each of the points x_k^* .

The reader who wishes to base a proof upon the stated property of the extremal solution should consult a note by Helly,¹³ where a system of integral equations is studied from the same point of view; by analogy it corresponds to the case $p = 1$, which we shall consider later. It should also be observed that, when the data are real—as is also the case in the note just cited—the circles may be replaced by segments of the real axis, and the necessary geometric considerations become much simpler.

Homogeneous systems

46. One may also ask whether system (8) possesses, besides (x_k^*) , other admissible solutions, that is, solutions for which $\sum |x_k|^p$ converges. This question is equivalent to asking whether the homogeneous system

$$\sum_{k=1}^{\infty} a_{ik} x_k = 0 \quad (i = 1, 2, \dots) \quad (37)$$

possesses admissible solutions other than $x_1 = x_2 = \dots = 0$. Indeed, from every solution (x_k^0) of (37) one obtains a solution $(x_k^{**}) = (x_k^* + x_k^0)$ of (8); conversely, every solution (x_k^{**}) of (8) gives a solution $(x_k^0) = (x_k^{**} - x_k^*)$; and, by (5), (x_k^0) and (x_k^{**}) are either both admissible or both inadmissible.

The discussion of the homogeneous system (37) reduces to the following observation. If the system has a solution (x_k^0) distinct from the evident solution $x_1 = x_2 = \dots = 0$, then $x_k^0 \neq 0$ for one or more values of k ; fixing one of these values, say $k = k_1$, we may suppose that $x_{k_1}^0 = 1$. Consequently, the system obtained by adjoining to (37) the equation

$$x_{k_1} = 1$$

must satisfy, for some value of M , the condition for nonhomogeneous systems. Thus the existence of an index k_1 and a number M for which that condition is fulfilled is necessary and sufficient for (37) to possess an admissible solution other than $x_1 = x_2 = \dots = 0$.

¹³E. Helly, *Ueber lineare Funktionaloperationen*, *Sitzungsberichte d. k. Akademie d. Wiss., Wien*, vol. CXXI, IIa, February 1912.

For arbitrary p , the calculation of the solutions of the homogeneous system has many drawbacks. This is readily seen by comparing the general case with the case $p = 2$. I shall spare the reader this comparison; we shall return below to the case $p = 2$. In any event, one can formulate a kind of rule which displays all the solutions; this rule is purely theoretical in the general case, but it lends itself well to effective calculation when $p = 2$. Consider system (8), keep the a_{ik} fixed, and vary the c_i ; the number M^* may be regarded as a function of the c_i . Plainly this function is well defined for all systems (c_i) obtained from (8) by assigning to the x_k values for which $\sum |x_k|^p$ converges. Hence, substituting in the function

$$M^*(c_1, c_2, \dots)$$

the left-hand sides of (8) in place of the c_i , one obtains a function $F(x_1, x_2, \dots)$ of infinitely many variables x_k ; it satisfies

$$F(x_1, x_2, \dots) \leq \left[\sum_{k=1}^{\infty} |x_k|^p \right]^{1/p}. \quad (38)$$

Equality holds when (x_k) is the extremal solution of a system such as (8), with suitable c_i ; strict inequality holds when it is not. The homogeneous system (37) has no admissible solution other than $x_1 = x_2 = \dots = 0$ if and only if every system (x_k) belongs to the first category, that is, if equality holds without exception in (38). Otherwise (37) also has solutions distinct from $x_1 = x_2 = \dots = 0$. In every case, the totality of the solutions of (37) is given by the single equation

$$F(x_1, x_2, \dots) = 0.$$

The Case $p = 2$. Schmidt's Theory

47. We now pass to the most important special case, $p = 2$, and see what can be deduced for it from our general results.¹⁴

By (21), in the case under consideration the $x_k^{(n)}$ have the form

$$x_k^{(n)} = \left(\sum_{i=1}^n \mu_i c_i \right) \left(\sum_{i=1}^n \overline{\mu_i} \overline{a_{ik}} \right) = \sum_{i=1}^n \nu_i \overline{a_{ik}}. \quad (39)$$

¹⁴Besides the works of Hilbert and Schmidt already cited, see G. Kowalewski, *Einführung in die Determinantentheorie*, Leipzig, 1909, pp. 407–455; Bôcher and Brand, "On linear equations with an infinite number of variables," *Annals of Mathematics*, second series, vol. XIII (1912), pp. 167–186.

¹⁵Here and below, $\bar{a}$ denotes the conjugate of the complex number a .

The v_i are determined by the equations

$$\sum_{i=1}^n \alpha_{ij} v_i = c_j \quad (j = 1, 2, \dots, n), \quad \alpha_{ij} = \sum_{k=1}^{\infty} \overline{a_{ik}} a_{jk}. \quad (39)$$

These equations are obtained by replacing the x_k in (8) by the expressions $\sum v_i \overline{a_{ik}}$. Complete system (39) by adjoining the equation

$$\sum_{i=1}^n \overline{a_{ij}} v_i = x_j^{(n)},$$

and eliminate the v_i ; this gives

$$x_j^{(n)} = - \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} & c_1 \\ \vdots & & \vdots & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} & c_n \\ \overline{a_{1j}} & \cdots & \overline{a_{nj}} & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}}. \quad (40)$$

Moreover,

$$M^{(n)2} = \sum_{k=1}^{\infty} |x_k^{(n)}|^2 = \sum_{k=1}^{\infty} x_k^{(n)} \overline{x_k^{(n)}} = \sum_{i=1}^n v_i \left(\sum_{k=1}^{\infty} \overline{a_{ik}} \overline{x_k^{(n)}} \right) = \sum_{i=1}^n v_i \overline{c_i}.$$

Thus the v_i satisfy the equation

$$\sum_{i=1}^n v_i \overline{c_i} = M^{(n)2}.$$

Adjoining this equation to system (39) and eliminating the v_i , one obtains

$$M^{(n)2} = - \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} & c_1 \\ \vdots & & \vdots & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} & c_n \\ \overline{c_1} & \cdots & \overline{c_n} & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}}. \quad (41)$$

Now the Hermitian form⁸

$$\sum_{i,j=1}^n \alpha_{ij} v_i \overline{v_j} = \sum_{k=1}^{\infty} \left| \sum_{i=1}^n \overline{a_{ik}} v_i \right|^2$$

is manifestly positive; hence the determinant in the denominator is real and positive. It is understood that the left-hand sides of equations (15) are assumed independent, which is equivalent to assuming that $\det(\alpha_{ik})_{i,k=1}^n \neq 0$. Otherwise formulas (40) and (41) have no meaning. The modifications required in that case belong to the ordinary theory of linear equations, and we shall not dwell on them.

As in the general case, the extremal solutions $(x_k^{(n)})$ of the partial systems tend to the extremal solution (x_k^*) of the complete system, and do so in such a way that

$$\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} |x_k^* - x_k^{(n)}|^2 = 0.$$

Formula (41) also permits the solvability condition to be stated in a form no longer containing the indeterminates μ_i . Regard $M^{(n)}$ as a function of the c_i . For each system (c_i) , the sequence $M^{(1)} \leq M^{(2)} \leq M^{(3)} \leq \dots$ tends to a definite positive value, finite or infinite, denoted by M^* . Thus the formula

$$M^*(c_1, c_2, \dots) = \lim_{n \rightarrow \infty} \left\{ \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} & c_1 \\ \vdots & & \vdots & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} & c_n \\ \overline{c_1} & \cdots & \overline{c_n} & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}} \right\}^{1/2} \quad (42)$$

defines a function of infinitely many variables c_i . Accordingly, the necessary and sufficient condition for system (8) to possess a solution (x_k) such that

$$\sum_{k=1}^{\infty} |x_k|^2 \leq M^2 \quad (43)$$

⁸*Translator's note:* The French original omits the conjugation on a_{ik} in the sum on the right; it is inserted here so that the displayed identity agrees with the definition of α_{ij} .

is the inequality

$$M^*(c_1, c_2, \dots) \leq M.$$

All these details concern the general situation in which the left-hand sides are assumed independent. But the function $M^*(c_1, c_2, \dots)$ also exists in the contrary case; only slight changes to the preceding method are then required to calculate it.

48. To carry the study of systems (8) further, substitute in (42), in place of the c_i , the left-hand sides of (8), and in place of the $\bar{c}_i$ their conjugates. The result is the expression denoted in the general case by $F(x_1, x_2, \dots)$ in no. 46. This function F is the square root of the Hermitian form in infinitely many variables

$$\sum_{j,k=1}^{\infty} \Lambda_{jk} x_j \bar{x}_k, \quad \Lambda_{kj} = \overline{\Lambda_{jk}}, \quad (44)$$

whose coefficients, when the left-hand sides are independent, are calculated by

$$\Lambda_{jk} = - \lim_{n \rightarrow \infty} \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} & a_{1j} \\ \vdots & & \vdots & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} & a_{nj} \\ \overline{a_{1k}} & \cdots & \overline{a_{nk}} & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}}. \quad (45)$$

For every system of values (x_k) , the Hermitian form (44) remains at most $\sum |x_k|^2$. Equality holds only when (x_k) is the extremal solution of a system such as (8). The solutions of the homogeneous system

$$\sum_{k=1}^{\infty} a_{ik} x_k = 0 \quad (i = 1, 2, \dots)$$

are characterized by the fact that the Hermitian form (44) vanishes for these systems (x_k) and not for the others. The condition that the homogeneous system have no solution except the evident one is

$$\Lambda_{jk} = \begin{cases} 1, & j = k, \\ 0, & j \neq k. \end{cases}$$

Here is another simple interpretation of the coefficients Λ_{jk} . For a fixed index j , consider the system

$$\sum_{k=1}^{\infty} a_{ik} x_k = a_{ij} \quad (i = 1, 2, \dots). \quad (46)$$

This system plainly has the solution $x_k = 1$ for $k = j$ and $x_k = 0$ for $k \neq j$. On the other hand, to calculate its extremal solution one need only replace the c_i in formula (40) by the a_{ij} and let n increase indefinitely; comparison with (45) gives

$$x_k = \Lambda_{jk} \quad (k = 1, 2, \dots).$$

This is the desired extremal solution of (46). The difference between the two solutions of (46), namely $\Lambda_{j1}, \Lambda_{j2}, \dots, \Lambda_{jj} - 1, \dots$, therefore satisfies the homogeneous system. Thus each value of j gives one solution of the homogeneous system.

More generally, let (ξ_k) be any system of values for which $\sum |\xi_k|^2$ converges. The system

$$\sum_{k=1}^{\infty} a_{ik} x_k = \sum_{k=1}^{\infty} a_{ik} \xi_k \quad (i = 1, 2, \dots) \quad (47)$$

plainly has the solution $x_k = \xi_k$. Let us now evaluate its extremal solution. The first n equations of (47) have the extremal solution

$$x_k^{(n)} = \sum_{j=1}^{\infty} \Lambda_{jk}^{(n)} \xi_j \quad (k = 1, 2, \dots),$$

where $\Lambda_{jk}^{(n)}$ denotes the n th approximate value of Λ_{jk} occurring in (45). But $x_1 = \Lambda_{j1}^{(n)} = \overline{\Lambda_{1j}^{(n)}}$, $x_2 = \Lambda_{j2}^{(n)} = \overline{\Lambda_{2j}^{(n)}}$, $\dots$ is the extremal solution of the first n equations of (46); those equations also have the solution $x_k = 1$ for $k = j$ and $x_k = 0$ for $k \neq j$. Hence

$$\sum_{j=1}^{\infty} |\Lambda_{jk}^{(n)}|^2 \leq 1.$$

Consequently formula (28) applies: there one need only replace the a_k by the ξ_j , the y_k^* by the Λ_{jk} , and the $y_k^{(n)}$ by the $\Lambda_{jk}^{(n)}$. The desired extremal solution is therefore

$$x_k^* = \lim_{n \rightarrow \infty} x_k^{(n)} = \lim_{n \rightarrow \infty} \sum_{j=1}^{\infty} \Lambda_{jk}^{(n)} \xi_j = \sum_{j=1}^{\infty} \Lambda_{jk} \xi_j.$$

The difference between the two solutions just found for (47) satisfies the homogeneous system, and in fact gives its general solution. For if (x_k^0) is any solution of the homogeneous system, choose $\xi_k = -x_k^0$; then (47) becomes homogeneous, has $x_1 = x_2 = \dots = 0$ as its extremal solution, and the preceding procedure gives (x_k^0) .

Thus the formulas^h

$$x_k = -\xi_k + \sum_{j=1}^{\infty} \Lambda_{jk} \xi_j \quad (k = 1, 2, \dots)$$

include all solutions of the homogeneous system. Equivalently, every solution of the homogeneous system is a finite or infinite linear combination of the particular solutions $\Lambda_{j1}, \dots, \Lambda_{jj} - 1, \dots$ ($j = 1, 2, \dots$), the multipliers ξ_j being subject to the condition that $\sum |\xi_j|^2$ converge.

49. All these calculations simplify greatly in the special case in which

$$\alpha_{ij} = \sum_{k=1}^{\infty} a_{ik} \overline{a_{jk}} = \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases}$$

which Hilbert and Schmidt express by saying that the linear forms

$$\sum_{k=1}^{\infty} a_{ik} x_k \quad (i = 1, 2, \dots)$$

constitute an orthogonal and normalized system.

Formulas (40) and (41) give in this case

$$x_k^{(n)} = \sum_{i=1}^n \overline{a_{ik}} c_i, \quad M^{(n)2} = \sum_{i=1}^n |c_i|^2.$$

Consequently, the condition that the system possess a solution (x_k) satisfying (43) is

$$M^{*2} = \sum_{i=1}^{\infty} |c_i|^2 \leq M^2,$$

and the extremal solution (x_k^*) is

$$x_k^* = \sum_{i=1}^{\infty} \overline{a_{ik}} c_i \quad (k = 1, 2, \dots).$$

^hTranslator's note: The printed formula has $+\xi_k$, but the source copy carries a handwritten correction to $-\xi_k$, as required by the preceding choice $\xi_k = -x_k^0$.

For this solution,

$$\sum_{k=1}^{\infty} |x_k^*|^2 = \sum_{i=1}^{\infty} |c_i|^2.$$

The coefficients of the Hermitian form (44) are

$$\Lambda_{jk} = \sum_{n=1}^{\infty} a_{nj} \overline{a_{nk}}. \quad (48)$$

If, under the present hypothesis, the homogeneous system has no solution other than $x_1 = x_2 = \cdots = 0$, we say that the system of left-hand sides is *complete*; for this is equivalent to the nonexistence of a linear form orthogonal to all the left-hand sides at once. As we have seen, this holds if and only if $\Lambda_{jk} = 1$ for $j = k$ and 0 for $j \neq k$. In view of (48), this condition may be stated by saying that the transposed forms

$$\sum_{i=1}^{\infty} a_{ik} x_i \quad (k = 1, 2, \dots)$$

also constitute an orthogonal and normalized system. This formulation is noteworthy because of its evident analogy with the familiar case of an orthogonal and normalized system of n linear forms in n variables. In that case completeness follows immediately because there are as many forms as variables; with infinitely many variables there is no analogous reason.

All these results concerning orthogonal systems can also be established directly and very simply. We shall not give the direct proof, which would merely repeat rapidly, with obvious changes, the arguments used in the general case.

50. The special case just considered was first discussed by Hilbert, who was led to it by ideas to which we shall return later. Schmidt studied this special case in greater detail and, moreover, succeeded in reducing the general case $p = 2$ to it.¹⁶ In his method the special case under consideration plays a very important role: he reduces the general case to it by a very simple process, *orthogonalization*. This process consists in replacing system (8) by an equivalent system

$$\sum_{k=1}^{\infty} b_{ik} x_k = d_i \quad (i = 1, 2, \dots), \quad (49)$$

whose left-hand sides are, on the one hand, linear combinations of those of equations (8), and, on the other hand, form an orthogonal and normalized system.

¹⁶See the memoir cited in no. 32.

More precisely, the n th equation in (49) is a linear combination of the first n equations in (8). For such a reduction to be possible, equations (8) (or rather every finite number of them) must be linearly independent; but we have seen that this restriction is only apparent. The multipliers, and hence the quantities b_{ik} and d_i , are easily found. To simplify the calculation we first form an intermediate system

$$\sum_{k=1}^{\infty} b'_{ik} x_k = d'_i \quad (i = 1, 2, \dots), \quad (50)$$

requiring only that its left-hand sides be orthogonal; to pass from it to the normalized system (49), each equation is divided by

$$\left[\sum_{k=1}^{\infty} |b'_{ik}|^2 \right]^{1/2}.$$

The data of such a system (50) are obtained from the linear equations expressing orthogonality by the formulas

$$b'_{nk} = \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{1n} & 0 \\ \vdots & & \vdots & \vdots \\ \alpha_{n1} & \cdots & \alpha_{nn} & 1 \\ a_{1k} & \cdots & a_{nk} & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{1n} \\ \vdots & & \vdots \\ \alpha_{n1} & \cdots & \alpha_{nn} \end{vmatrix}}, \quad d'_n = \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{1n} & 0 \\ \vdots & & \vdots & \vdots \\ \alpha_{n1} & \cdots & \alpha_{nn} & 1 \\ c_1 & \cdots & c_n & 0 \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{1n} \\ \vdots & & \vdots \\ \alpha_{n1} & \cdots & \alpha_{nn} \end{vmatrix}}.$$

The left-hand sides of equations (49) may also be calculated from

$$\left| \sum_{k=1}^{\infty} b_{nk} x_k \right|^2 = \sum_{j,k=1}^{\infty} (\Lambda_{jk}^{(n)} - \Lambda_{jk}^{(n-1)}) x_j \overline{x_k} \quad (n = 1, 2, \dots).$$

This is simply the evident fact that two equivalent systems always lead to the same Hermitian form (44).

Having transformed system (8) in this manner into the special system (49), its discussion and solution proceed, as we have seen, by very simple formulas. Substitution in those formulas of the expressions for b and d in terms of a and c recovers the formulas established above by another method.

But this is only the principal idea of Schmidt's work which we have just described; for the details we must refer the reader to the original memoir. One of its most interesting features is that it sees and speaks as though the subject were geometry. To fix ideas, suppose that all quantities are real. Interpret systems (a_k) or (x_k) , whenever $\sum a_k^2$ or $\sum x_k^2$ converges, as vectors in a space of infinitely many dimensions. Given finitely or infinitely many vectors, the vectors orthogonal to each of them constitute a certain linear manifold, and the set of vectors orthogonal to this latter manifold is the smallest linear manifold containing the given vectors. Thus, to solve a homogeneous system, one need only regard its coefficients as the coordinates of vectors; the manifold orthogonal to these vectors represents the totality of the solutions. Nonhomogeneous systems may be made homogeneous by introducing an auxiliary unknown. Finally, orthogonalization amounts in principle to replacing the given system of vectors by a system of mutually orthogonal vectors in such a way that the two systems determine the same linear manifold.

The Cases $p = 1$ and $p \rightarrow \infty$

51. Consider first the case $p = 1$. It was not included in the preceding arguments, which applied only to $p > 1$, but it enters as a limiting case.

Here one seeks a solution (x_k) of system (8) for which the series

$$\sum_{k=1}^{\infty} |x_k| \quad (51)$$

converges. As regards the data, we assume that, for every i ,

$$\lim_{k \rightarrow \infty} a_{ik} = 0.$$

The reason is as follows. If the series

$$\sum_{k=1}^{\infty} a_k x_k \quad (52)$$

were merely required to converge for every system (x_k) for which (51) exists, it would suffice to suppose the quantities $|a_k|$ bounded as a whole. But, just as above, we also need this series to converge uniformly for all systems (x_k) such that

$$\sum_{k=1}^{\infty} |x_k| \leq G.$$

In particular, convergence must be uniform for all systems in which one x_k equals G and all the others are zero. Substitute these values in turn in (52); the n th remainders are respectively

$$0, \dots, 0, Ga_{n+1}, Ga_{n+2}, \dots$$

Uniform convergence holds if and only if, as $n \rightarrow \infty$, these remainders tend uniformly to zero. This is equivalent to assuming, as above, that

$$a_k \rightarrow 0.$$

With this restriction, all the auxiliary arguments used in the general case extend, *mutatis mutandis*, to $p = 1$.

52.

Theorem. *A necessary and sufficient condition for system (8) to possess a solution (x_k) such that*

$$\sum_{k=1}^{\infty} |x_k| \leq M \quad (53)$$

is that

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq M \sup_{k=1,2,\dots} \left| \sum_{i=1}^n \mu_i a_{ik} \right| \quad (54)$$

for every n and every choice of the μ_i .

The condition is plainly necessary. To prove it sufficient, it is enough to consider n equations, since passage to infinitely many equations is made exactly as for $p > 1$.

From the hypothesis $a_{ik} \rightarrow 0$ it follows at once that there is a number m such that the value of

$$\sup_{k=1,2,\dots} \left| \sum_{i=1}^n \mu_i a_{ik} \right|$$

depends only on indices $k \leq m$. This permits us to replace the system with infinitely many unknowns by one with m unknowns,

$$\sum_{k=1}^m a_{ik} x_k = c_i \quad (i = 1, 2, \dots, n). \quad (55)$$

Indeed, if (55) has a solution (x_k) such that

$$\sum_{k=1}^m |x_k| \leq M,$$

then, putting $x_{m+1} = x_{m+2} = \dots = 0$, we obtain a solution of the original system satisfying (53). By the stated property of m , condition (54) holds for the reduced system (55).ⁱ On the other hand, for every $p > 1$,

$$\sup_{k=1, \dots, m} \left| \sum_{i=1}^n \mu_i a_{ik} \right| \leq \left[\sum_{k=1}^m \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right]^{(p-1)/p}.$$

Consequently, for every $p > 1$ the data of (55) satisfy

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq M \left[\sum_{k=1}^m \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right]^{(p-1)/p}.$$

But this is precisely the condition that (55) possess a solution $(x_k^{(p)})$ such that

$$\sum_{k=1}^m |x_k^{(p)}|^p \leq M^p. \quad (56)$$

Thus, for each $p > 1$, there exists a solution $(x_k^{(p)})$ satisfying (56); for definiteness one may take, for example, the extremal solutions.

The quantities $|x_k^{(p)}| \leq M$ are bounded as a whole. Hence there is a sequence of exponents $p_1, p_2, \dots$ tending to 1 such that the limits

$$x_k^* = \lim_{p_v \rightarrow 1} x_k^{(p_v)} \quad (k = 1, \dots, m)$$

exist. Since every system $(x_k^{(p_v)})$ satisfies (55), the limiting system (x_k^*) does also. Moreover,

$$\sum_{k=1}^m |x_k^*| = \lim_{p_v \rightarrow 1} \sum_{k=1}^m |x_k^{(p_v)}|^{p_v} \leq \lim_{p \rightarrow 1} M^p = M.$$

The sufficiency of the condition is therefore proved.

ⁱTranslator's note: The French text refers here to system (56), evidently a misprint for the reduced system (55).

53. A second limiting case corresponds to $p \rightarrow \infty$. Much less is required of the solution (x_k) than in the cases already treated: it is required only that the values (x_k) be bounded as a whole. As for the data, the only assumption is that the left-hand sides of equations (8) converge for every bounded system (x_k) . This amounts to supposing that all the series $\sum_k |a_{ik}|$ ($i = 1, 2, \dots$) converge.

Theorem. *The necessary and sufficient condition for system (8) to possess a solution (x_k) such that $|x_k| \leq M$ for every k is that*

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq M \sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right| \quad (57)$$

for every n and every choice of the μ_i .

The passage from finitely many equations to infinitely many being almost the same as in the other cases, it is enough to study n equations.

The condition is plainly necessary. To prove sufficiency, suppose that it holds and also suppose (as we know this entails no loss of generality) that there is no linear relation among the left-hand sides of the equations. Then the ratio

$$\frac{\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|}{\left[\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right]^{(p-1)/p}}$$

tends to 1 as $p \rightarrow \infty$, uniformly for every choice of the μ_i . Inequality (57) may therefore be replaced by

$$\left| \sum_{i=1}^n \mu_i c_i \right| \leq (M + \varepsilon) \left[\sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^{p/(p-1)} \right]^{(p-1)/p},$$

where ε is an arbitrarily small positive quantity and p is sufficiently large. This modified inequality is precisely the condition that our system of equations possess a solution (x_k) such that

$$\sum_{k=1}^{\infty} |x_k|^p \leq (M + \varepsilon)^p.$$

Let (x_k^ε) be such a solution; plainly $|x_k^\varepsilon| \leq M + \varepsilon$ for every k . Letting ε tend to zero yields an infinite sequence of solutions $(x_k^{(\varepsilon)})$. Then, by applying a procedure analogous to that of [no. 41](#), one selects a subsequence such that, for every k , $x_k^{(\varepsilon)}$ tends to a limit x_k^* . The system (x_k^*) is then the required solution.

It remains to observe that, whereas in the general case $p > 1$ the extremal solution was always unique, this is no longer so in the two limiting cases just considered. The reason is readily seen. For example, in the case $p = 1$, it is the fact that in $\sum |a_k + b_k| \leq \sum |a_k| + \sum |b_k|$, equality may hold without all the ratios $a_k : b_k$ being equal.

Chapter IV.

Theory of Linear Substitutions in Infinitely Many Variables

Linear Substitutions

54. The criteria established in the [preceding chapter](#) relate to very broadly conceived systems of equations. We shall now restrict ourselves to the case in which $p = p/(p-1) = 2$. Most of the arguments, however, extend without essential alteration to every $p > 1$, and even to the two limiting cases.

We shall call the aggregate of all systems (x_k) for which $\sum_k |x_k|^2$ converges the *Hilbert space*. A correspondence which assigns to every element (x_k) of this space one and only one element (x'_k) of the same space will be called a *linear substitution* if it has the following properties. First, it is distributive: the elements corresponding to (cx_k) and $(x_k + y_k)$ are respectively (cx'_k) and $(x'_k + y'_k)$. In algebra, where only finitely many variables occur, distributivity also entails continuity. Here continuity must be assumed explicitly. Secondly, it is continuous: whenever a sequence of elements tends to a limiting element, the corresponding sequence of transformed elements tends to the element corresponding to that limit. Such distributive and continuous correspondences will henceforth be called linear substitutions.

55. Let us recall that the convergence of $(x_k^{(n)})$ to (x_k) means that $x_k^{(n)} \rightarrow x_k$ for every fixed k and that the sums $\sum_k |x_k^{(n)}|^2$ remain bounded uniformly in n ([no. 40](#)). Continuity then implies the existence of a finite constant M such that

$$\sum_{k=1}^{\infty} |x'_k|^2 \leq M^2 \sum_{k=1}^{\infty} |x_k|^2. \quad (1)$$

Indeed, otherwise there would be a sequence of elements $(x_k^{(n)})$ and the corresponding sequence $(x_k^{(n)'})$ such that $\sum_k |x_k^{(n)}|^2$ remained bounded, while $\sum_k |x_k^{(n)'}|^2$ increased beyond every bound as $n \rightarrow \infty$. By the selection principle of [no. 41](#), one could extract from the former a subsequence converging to an element; the corre-

sponding sequence, lacking property 2° , could converge to no element. Continuity would therefore fail.

The least admissible value of M will be called the *bound* of the substitution A and will be denoted by M_A .

56. We shall say that $(x_k^{(n)})$ tends *strongly* to (x_k) if

$$\sum_{k=1}^{\infty} |x_k - x_k^{(n)}|^2 \longrightarrow 0. \quad (2)$$

Since a linear substitution is distributive, the element corresponding to $(x_k - x_k^{(n)})$ is $(x'_k - x_k^{(n)'})$; hence

$$\sum_{k=1}^{\infty} |x'_k - x_k^{(n)'}|^2 \leq M^2 \sum_{k=1}^{\infty} |x_k - x_k^{(n)}|^2 \longrightarrow 0.$$

Thus a linear substitution also preserves strong convergence.

The reduced elements

$$(x_1, x_2, \dots, x_n, 0, 0, \dots)$$

tend strongly to (x_k) . If $(a_{ik})_{i=1}^{\infty}$ denotes the element corresponding to the element whose k th coordinate is 1 and whose other coordinates vanish,^j distributivity and the preceding observation give

$$\sum_{i=1}^{\infty} \left| x'_i - \sum_{k=1}^n a_{ik} x_k \right|^2 \longrightarrow 0, \quad (3)$$

and consequently

$$x'_i = \sum_{k=1}^{\infty} a_{ik} x_k \quad (i = 1, 2, \dots). \quad (4)$$

Every linear substitution therefore corresponds to a matrix (a_{ik}) for which the series in (4) converge and

$$\sum_{i=1}^{\infty} \left| \sum_{k=1}^{\infty} a_{ik} x_k \right|^2 \leq M^2 \sum_{k=1}^{\infty} |x_k|^2. \quad (5)$$

^jTranslator's note: The French text says that the j th coordinate is 1 when $j = i$; the column $(a_{ik})_i$ and formula (4) show that $j = k$ is intended.

Conversely, a matrix satisfying (5) for every element of Hilbert space defines by (4) a bounded distributive, and hence continuous, correspondence; the continuity of the individual linear forms follows from the results of the [preceding chapter](#).

Inequality (5), required for every element (x_k) , is plainly equivalent to

$$\sum_{i=1}^m \left| \sum_{k=1}^n a_{ik} x_k \right|^2 \leq M^2 \sum_{k=1}^n |x_k|^2,$$

required for every choice of the integers m, n and of the quantities $x_1, \dots, x_n$. We thus have the following rule.

Theorem. *A matrix (a_{ik}) defines a linear substitution A with $M_A \leq M$ if and only if*

$$\sum_{i=1}^m \left| \sum_{k=1}^n a_{ik} x_k \right|^2 \leq M^2 \sum_{k=1}^n |x_k|^2$$

for every choice of the integers m, n and of the quantities $x_1, \dots, x_n$.

57. We should mention here a very remarkable fact discovered by Hellinger and Toeplitz. Instead of assuming inequality (5), it is enough to suppose that its left-hand side converges for every (x_k) . The existence of a finite constant M_A follows from this last hypothesis by a very delicate argument. The authors stated their theorem in a slightly different form, connecting it with the notion of a bilinear form which we shall meet in the next section.¹

¹Hellinger and Toeplitz, *Grundlagen für eine Theorie der unendlichen Matrizen*, *Mathematische Annalen*, vol. 69, pp. 289–330. They consider the expression

$$\sum_{i=1}^{\infty} \left(\sum_{k=1}^{\infty} a_{ik} x_k \right) y_i$$

and suppose that it converges for all elements $(x_k), (y_k)$ of Hilbert space. By a much simpler theorem of the same authors, discussed in the [preceding chapter](#) (no. 35), convergence of $\sum_i b_i y_i$ for every element (y_i) entails convergence of $\sum_i |b_i|^2$. This reduces their hypothesis to the one in the text.

Here, in a few words, is the idea of the proof. Contrary to what is to be proved, suppose that

$$\frac{\sum_{i=1}^{\infty} \left| \sum_{k=1}^{\infty} a_{ik} x_k \right|^2}{\sum_{k=1}^{\infty} |x_k|^2}$$

Let us add that, in the definition of linear substitutions, the first definition of continuity used above could be replaced by one based upon strong convergence. The correspondence would be called continuous when, whenever $(x_k^{(n)})$ tends strongly to (x_k) in the sense of (2), the corresponding $(x_k^{(n)'})$ tends strongly to (x'_k) . Only the definition would change: the two definitions being equivalent, the notion itself remains completely unaltered.

can exceed every finite bound. The analogous expressions in which the summations begin only with $i = m$, $k = n$ have the same property. On the other hand, for a fixed element (x_k) , restricting the summations to sufficiently large finite indices m' , n' does not appreciably alter the value. These facts permit one to choose successively indices $i_1, k_1, i_2, k_2, \dots$ and quantities $x_1, \dots, x_{k_1}, \dots, x_{k_2}, \dots$ so that $\sum_k |x_k|^2$ converges, while

$$\sum_{i=i_v+1}^{i_{v+1}} \left| \sum_{k=k_v+1}^{k_{v+1}} a_{ik} x_k \right|^2$$

increases rapidly with v , and at the same time

$$\sum_{i=i_v+1}^{i_{v+1}} \left| \sum_{k=1}^{\infty} a_{ik} x_k \right|^2$$

depends appreciably only upon the terms whose indices lie between $k_v + 1$ and k_{v+1} . For this particular element the left-hand side of (5) therefore diverges.

This reasoning is closely related to a still little-known argument of Lebesgue, who connects the existence of continuous 2π -periodic functions whose Fourier series diverges or fails to converge uniformly with the fact that the supremum of the absolute value of the n th partial sums, over continuous 2π -periodic functions satisfying $|f| \leq 1$, increases without bound with n ; see Lebesgue, *Sur la divergence et convergence non uniforme des séries de Fourier*, *Comptes rendus*, 1905, second semester, pp. 875–877, and *Leçons sur les séries trigonométriques*, p. 86. Fejér has recently carried Lebesgue's idea further, and Haar and Lebesgue himself extended it to analogous problems; see Haar, *Zur Theorie der orthogonalen Funktionensysteme*, Göttingen thesis, 1909 (reprinted in *Mathematische Annalen*, vol. 69, pp. 331–371); Lebesgue, *Sur les intégrales singulières*, *Annales de la Faculté des Sciences de Toulouse*, 3rd series, vol. 1 (1910), pp. 25–117; and Fejér, *Sur les singularités de la série de Fourier des fonctions continues*, *Annales de l'École Normale*, 3rd series, vol. 28 (1911), pp. 63–104, where earlier work is also listed. These investigations do not belong to the subject of this book; they are mentioned in the hope that their study may suggest applying the Hellinger–Toeplitz method to many questions of the present theory and, in particular, extending their theorem to every case $p \geq 1$.

Bilinear Forms and Transposed Substitutions

58. The theory of matrices (a_{ik}) of the kind considered here is due to Hilbert. His formal point of departure differs from ours. He considers the infinite bilinear form

$$A(x, y) = \sum_{i,k=1}^{\infty} a_{ik} x_k y_i, \quad (6)$$

and assumes that the absolute values of the reductions

$$[A(x, y)]_n = \sum_{i,k=1}^n a_{ik} x_k y_i,$$

formed for every n and all elements $(x_k), (y_k)$ satisfying

$$\sum_{k=1}^{\infty} |x_k|^2 \leq 1, \quad \sum_{k=1}^{\infty} |y_k|^2 \leq 1, \quad (7)$$

remain below a positive constant M . The convergence of the series (4) and inequality (5) follow at once; hence Hilbert's matrices define linear substitutions. Conversely, if our point of departure is adopted, every linear substitution leads, by the analysis of no. 56, to a uniquely determined matrix (a_{ik}) ; inequality (5), together with the Cauchy–Lagrange inequality, places us under Hilbert's hypothesis. These two inequalities assure at the same time the convergence of

$$\sum_{i=1}^{\infty} \left(\sum_{k=1}^{\infty} a_{ik} x_k \right) y_i$$

and show that its absolute value is at most M . Formula (6) and the Cauchy–Lagrange inequality give

$$\begin{aligned} \sum_{i=1}^{\infty} \left(\sum_{k=1}^{\infty} a_{ik} x_k \right) y_i &= \lim_{n \rightarrow \infty} \sum_{k=1}^n \left(\sum_{i=1}^{\infty} a_{ik} y_i \right) x_k \\ &= \sum_{k=1}^{\infty} \left(\sum_{i=1}^{\infty} a_{ik} y_i \right) x_k. \end{aligned} \quad (8)$$

More generally,

$$\left| \sum_{i=1}^{m+p} \sum_{k=1}^{n+q} a_{ik} x_k y_i - \sum_{i=1}^m \sum_{k=1}^n a_{ik} x_k y_i \right|$$

$$\begin{aligned}
&\leq \left| \sum_{i=1}^m \sum_{k=n+1}^{n+q} a_{ik} x_k y_i \right| + \left| \sum_{i=m+1}^{m+p} \sum_{k=1}^{n+q} a_{ik} x_k y_i \right| \\
&\leq M \left(\sum_{k=n+1}^{n+q} |x_k|^2 \right)^{1/2} + M \left(\sum_{i=m+1}^{m+p} |y_i|^2 \right)^{1/2}.
\end{aligned}$$

It follows that the limit

$$\lim_{m,n \rightarrow \infty} \sum_{i=1}^m \sum_{k=1}^n a_{ik} x_k y_i \quad (9)$$

exists independently of the manner in which m and n tend to infinity; under (7) its numerical value does not exceed M .

Returning to the more special formula (8), we may interpret it as follows. Besides the substitution (4), the matrix (a_{ik}) defines a second linear substitution

$$y''_k = \sum_{i=1}^{\infty} a_{ik} y_i, \quad (10)$$

and the two substitutions are related by

$$\sum_{i=1}^{\infty} x'_i y_i = \sum_{k=1}^{\infty} x_k y''_k. \quad (11)$$

We shall say that the substitutions (4) and (10) are transposes of one another. For brevity, the former will be denoted by A and its transpose by $\mathfrak{A}$. Their bounds satisfy

$$M_A = M_{\mathfrak{A}}.$$

Inversion of Linear Substitutions

59. As in algebra, the *product* of two linear substitutions A, B is the linear substitution obtained by performing them successively:

$$AB(x_k) = A[B(x_k)].$$

In general this product depends upon the order of its factors. If (a_{ik}) , (b_{ik}) , and (c_{ik}) are the matrices corresponding to A , B , and $C = AB$, respectively, then

$$c_{ik} = \sum_{j=1}^{\infty} a_{ij} b_{jk} \quad (i, k = 1, 2, \dots).$$

If $\mathfrak{A}$ and $\mathfrak{B}$ are the transposes of A and B , the transpose of AB is $\mathfrak{B}\mathfrak{A}$.

We denote by E the identity substitution $x'_k = x_k$ ($k = 1, 2, \dots$); its matrix (e_{ik}) has $e_{ik} = 1$ when $i = k$ and $e_{ik} = 0$ when $i \neq k$.

60. Given a linear substitution A , we seek its reciprocal, or inverse, A^{-1} , satisfying

$$A^{-1}A = AA^{-1} = E. \quad (12)$$

When it exists, A^{-1} is uniquely determined by (12); in fact either one of the two relations alone already determines it, provided an inverse is known to exist. For if $DA = E$, then $D = DE = DAA^{-1} = EA^{-1} = A^{-1}$. Suppose therefore that A^{-1} exists, and let $\mathfrak{A}'$ temporarily denote its transpose. The substitutions $\mathfrak{A}\mathfrak{A}'$ and $\mathfrak{A}'\mathfrak{A}$ are the transposes of $A^{-1}A = E$ and $AA^{-1} = E$; hence

$$\mathfrak{A}\mathfrak{A}' = \mathfrak{A}'\mathfrak{A} = E.$$

Thus $\mathfrak{A}'$ is the inverse of $\mathfrak{A}$ and may be denoted by $\mathfrak{A}^{-1}$.

Let $1/m$ be a common bound for A^{-1} and $\mathfrak{A}^{-1}$. If A maps (x_k) to (x'_i) and $\mathfrak{A}$ maps (y_i) to (y''_k) , then

$$m^2 \sum_{k=1}^{\infty} |x_k|^2 \leq \sum_{i=1}^{\infty} |x'_i|^2 = \sum_{i=1}^{\infty} \left| \sum_{k=1}^{\infty} a_{ik} x_k \right|^2, \quad (13)$$

$$m^2 \sum_{i=1}^{\infty} |y_i|^2 \leq \sum_{k=1}^{\infty} |y''_k|^2 = \sum_{k=1}^{\infty} \left| \sum_{i=1}^{\infty} a_{ik} y_i \right|^2. \quad (14)$$

These inequalities give a necessary condition for the existence of A^{-1} : the two quotients

$$\frac{\sum_i \left| \sum_k a_{ik} x_k \right|^2}{\sum_k |x_k|^2}, \quad \frac{\sum_k \left| \sum_i a_{ik} y_i \right|^2}{\sum_i |y_i|^2}$$

must remain above some fixed number $m^2 > 0$. We shall show that this condition is also sufficient.

Suppose it is satisfied, and consider systems (4) and (10), regarding a_{ik} , x'_i , and y''_k as given. In (11) put $\mu_1, \dots, \mu_n, 0, 0, \dots$ in place of the y_i . Applying the Cauchy–Lagrange inequality gives

$$\left| \sum_{i=1}^n \mu_i x'_i \right|^2 \leq \sum_{i=1}^n |\mu_i|^2 \sum_{i=1}^{\infty} |x'_i|^2 \leq \frac{1}{m^2} \sum_{i=1}^{\infty} |x'_i|^2 \sum_{k=1}^{\infty} \left| \sum_{i=1}^n \mu_i a_{ik} \right|^2.$$

This is precisely the condition for system (4) to possess a solution (x_k) such that

$$\sum_{k=1}^{\infty} |x_k|^2 \leq \frac{1}{m^2} \sum_{i=1}^{\infty} |x'_i|^2. \quad (15)$$

Consequently, for every given element (x'_i) , system (4) has at least one solution satisfying (15). Likewise, for every given (y''_k) , system (10) has at least one solution (y_i) such that

$$\sum_{i=1}^{\infty} |y_i|^2 \leq \frac{1}{m^2} \sum_{k=1}^{\infty} |y''_k|^2. \quad (16)$$

The solutions of (4) and (10) are unique. For if, for example, (4) had two distinct solutions, its homogeneous system would have a nonzero solution; but for the homogeneous system the right-hand side of (15) vanishes, a contradiction. Thus each given (x'_i) determines one element (x_k) , and each given (y''_k) one element (y_i) . These correspondences are distributive, by uniqueness, and bounded by (15) and (16). They are therefore linear substitutions, and by their definition they are precisely A^{-1} and $\mathfrak{A}^{-1}$.

61. The entries $a_{ik}^{(-1)}$ of the matrix corresponding to A^{-1} and $\mathfrak{A}^{-1}$ may be calculated from system (4) (or from (10)): $a_{ik}^{(-1)}$ is the value of x_k obtained after putting $x'_i = 1$ and $x'_j = 0$ for $j \neq i$. Once the $a_{ik}^{(-1)}$ have been found in this way, A^{-1} and $\mathfrak{A}^{-1}$ are represented by

$$x_k = \sum_{i=1}^{\infty} a_{ik}^{(-1)} x'_i, \quad y_i = \sum_{k=1}^{\infty} a_{ik}^{(-1)} y''_k.$$

Formula (40) of the [preceding chapter](#) gives ^k

$$a_{ik}^{(-1)} = \lim_{n \rightarrow \infty} \frac{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1,i-1} & \cdots & \alpha_{n,i-1} \\ \overline{a_{1k}} & \cdots & \overline{a_{nk}} \\ \alpha_{1,i+1} & \cdots & \alpha_{n,i+1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}}{\begin{vmatrix} \alpha_{11} & \cdots & \alpha_{n1} \\ \vdots & & \vdots \\ \alpha_{1n} & \cdots & \alpha_{nn} \end{vmatrix}}, \quad \alpha_{ij} = \sum_{k=1}^{\infty} \overline{a_{ik}} a_{jk}.$$

The criterion just established may also be expressed as follows. Consider the two infinite Hermitian forms

$$\sum_{i=1}^{\infty} \left| \sum_{k=1}^{\infty} a_{ik} x_k \right|^2, \quad \sum_{k=1}^{\infty} \left| \sum_{i=1}^{\infty} a_{ik} x_i \right|^2. \quad (17)$$

The inequalities (13)–(14) state that both forms remain at least $m^2 > 0$ for every element (x_k) satisfying

$$\sum_{k=1}^{\infty} |x_k|^2 = 1. \quad (18)$$

When this is so, A has an inverse A^{-1} ; the lower limits of the two Hermitian forms under condition (18) are equal, and the reciprocal of their common square root is the bound $M_{A^{-1}}$.

62. The criterion just obtained appears here as a particular consequence of the general results of the [preceding chapter](#). Historically, however, it was discovered by Toeplitz independently of that general theory, and even before the latter had been developed.² Another very simple and interesting proof is due to Hilb.³ Those

^kTranslator's note: In the French original the row involving a_{ik} is placed last, its entries carry i instead of k , and the quotient has a prefixed minus sign. Expanding formula (40) gives the corrected row position, index, and sign used here.

²Toeplitz, *Die Jacobische Transformation der quadratischen Formen von unendlich vielen Veränderlichen, Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen*, 1907, pp. 101–109.

³Hilb, *Ueber die Auflösung von Gleichungen mit unendlich vielen Unbekannten, Sitzungsberichte der Physikalisch-Medizinischen Sozietät zu Erlangen*, 1908, pp. 84–89.

two proofs do not appear susceptible of extension to more general cases, whereas ours extends immediately to every $p \geq 1$.

To approach Toeplitz's line of thought, let b_{ik} and c_{ik} be the coefficients of $x_i \bar{x}_k$ in the two Hermitian forms (17), and let B, C denote the corresponding substitutions. Writing $\bar{\mathfrak{A}}$ for the substitution corresponding to the conjugate-transposed matrix, we have

$$B = \bar{\mathfrak{A}}A, \quad C = A\bar{\mathfrak{A}}.$$

If A^{-1} exists, then clearly

$$B^{-1} = A^{-1}\bar{\mathfrak{A}}^{-1}, \quad C^{-1} = \bar{\mathfrak{A}}^{-1}A^{-1}.$$

Conversely, if B and C have inverses, then A has the left inverse $B^{-1}\bar{\mathfrak{A}}$ and the right inverse $\bar{\mathfrak{A}}C^{-1}$; these are equal, since

$$(B^{-1}\bar{\mathfrak{A}})A = B^{-1}(\bar{\mathfrak{A}}A) = B^{-1}B = E, \quad A(\bar{\mathfrak{A}}C^{-1}) = (A\bar{\mathfrak{A}})C^{-1} = CC^{-1} = E,$$

and

$$B^{-1}\bar{\mathfrak{A}} = B^{-1}\bar{\mathfrak{A}}CC^{-1} = B^{-1}\bar{\mathfrak{A}}A\bar{\mathfrak{A}}C^{-1} = E\bar{\mathfrak{A}}C^{-1} = \bar{\mathfrak{A}}C^{-1}.$$

Everything is thus reduced to proving the following proposition.

Theorem. *If, as (x_k) varies under condition (18), the positive Hermitian form*

$$B(x, \bar{x}) = \sum_{i,k=1}^{\infty} b_{ik} x_i \bar{x}_k \quad (19)$$

has a lower limit $J > 0$, then the linear substitution $B = (b_{ik})$ has an inverse B^{-1} .

For this purpose consider the reductions

$$[B(x, \bar{x})]_n = \sum_{i,k=1}^n b_{ik} x_i \bar{x}_k. \quad (20)$$

Under the condition $\sum_{k=1}^n |x_k|^2 = 1$, these have lower limits J_n . Plainly $J_n \geq J$; moreover, the J_n form a decreasing sequence and in fact tend to J , though this last fact is not needed below. What is essential is that all J_n remain above a positive lower bound.

Let B_n be the linear substitution in n variables with coefficients b_{ik} ($i, k = 1, \dots, n$). The finite-dimensional analogue of the proposition follows at once from determinant theory. Since $J_n > 0$, the homogeneous system

$$\sum_{i=1}^n b_{ik} x_i = 0 \quad (k = 1, \dots, n)$$

has only the solution $x_1 = \cdots = x_n = 0$; hence the determinant $|b_{ik}|_n$ does not vanish and B_n has a well-defined inverse B_n^{-1} . Its bound is $1/J_n$.⁴

Let n increase without limit. The coefficients of B_n^{-1} tend to well-defined limits $b_{ik}^{(-1)}$, and the matrix $(b_{ik}^{(-1)})$ defines a linear substitution B^{-1} , which is the inverse of B . In short, in the present case the principle of reductions applies.

All this follows immediately from the principles of the [preceding chapter](#), especially the theorems of [nos. 40 and 42](#). A direct proof conforming to those principles would be just as easy, but its details would take us far from Toeplitz's line of thought. Toeplitz places himself at the standpoint of pure algebra, draws from it everything possible, and uses unlimited algorithms only when the power of algebraic methods has been exhausted.

There is in fact a considerable class of linear substitutions whose inversion, as regards the computation of coefficients, is accomplished by finite algorithms. Consider a substitution D such that, for every n , x'_n depends only on $x_1, \dots, x_n$. In its matrix (d_{ik}) all entries to the right of the diagonal vanish. When the inverse D^{-1} exists, its coefficients require only the solution of linear systems with finitely many unknowns; the coefficients of D_n^{-1} are at the same time those of D^{-1} .

There is another problem requiring only finite algorithms: decompose the substitution B in the form

$$B = DD^*,$$

where D is of the triangular type just considered and D^* is its conjugate transpose. The coefficients d_{ik} are obtained successively by making the analogous decompositions of the substitutions B_n .

From this standpoint, inversion of B consists first in forming the decomposition $B = DD^*$, then determining D^{-1} , and finally—only here are unlimited algorithms used—forming the product $(D^*)^{-1}D^{-1}$. This product is plainly B^{-1} . It is understood

⁴For the purpose at hand it is enough to know that this bound does not exceed $1/J_n$, since we need only show that the upper bound does not increase without limit with n . If one is content with this inequality rather than exact equality, the Cauchy-Lagrange inequality gives, with $x'_i = \sum_{k=1}^n b_{ik}\bar{x}_k$,

$$J_n^2 \left(\sum_{i=1}^n |x_i|^2 \right)^2 \leq \left(\sum_{i,k=1}^n b_{ik} x_i \bar{x}_k \right)^2 \leq \sum_{i=1}^n |x_i|^2 \sum_{i=1}^n \left| \sum_{k=1}^n b_{ik} \bar{x}_k \right|^2 = \sum_{i=1}^n |x_i|^2 \sum_{i=1}^n |x'_i|^2,$$

whence

$$\frac{\sum_i |x_i|^2}{\sum_i |x'_i|^2} \leq \frac{1}{J_n^2}.$$

that these operations lead to bounded, hence linear, substitutions; this is easily verified.

Toeplitz calculates the coefficients of D^{-1} by decomposing the B_n^{-1} rather than the B_n . Let Δ_n be the determinant of the first n rows and columns of (b_{ik}) , and let $\binom{i}{k}_n$ denote its first-order minors. Put¹

$$d_{11}^{(-1)} = \frac{1}{\sqrt{b_{11}}}, \quad d_{ik}^{(-1)} = \frac{\binom{i}{k}_i}{\sqrt{\Delta_{i-1}\Delta_i}} \quad (i > 1, 1 \leq k \leq i), \quad d_{ik}^{(-1)} = 0 \quad (i < k).$$

If $D_1^{-1}, D_2^{-1}, \dots$ are the substitutions in 1, 2, $\dots$ variables formed with these coefficients, an identity going back to Lagrange gives

$$\sum_{i=1}^n \left| \sum_{k=1}^i d_{ik}^{(-1)} x_k \right|^2 = \frac{1}{\Delta_n} \sum_{i,k=1}^n \binom{i}{k}_n x_i \bar{x}_k;$$

that is, $(D_n^*)^{-1} D_n^{-1} = B_n^{-1}$.⁵

63. Unlike the method just sketched, Hilb's method belongs to analysis. It is based on the study of the series

$$E + A + A^2 + A^3 + \dots, \quad (21)$$

where $A^2, A^3, \dots$ denote the iterated substitutions

$$A^2 = AA, \quad A^3 = AA^2 = A^2A = AAA, \quad \dots$$

At first sight (21) is merely a formal expansion of $(E - A)^{-1}$, analogous to the power-series expansion of $(1 - z)^{-1}$. Hilb uses the fact that, as long as $M_A < 1$, the series converges and gives the inverse of $E - A$. We shall return later to the precise meaning of this statement. For the moment it is enough to note that it implies, among other things, that the coefficients of

$$S_n = E + A + \dots + A^{n-1}$$

tend to definite limits s_{ik} , and that these are exactly the coefficients of the inverse sought.

¹*Translator's note:* The French original gives the condition $i \geq k > 1$, which omits every $d_{i1}^{(-1)}$ with $i > 1$. The identity immediately below requires the corrected condition $i > 1, 1 \leq k \leq i$.

⁵The systems of equations corresponding to substitutions of the type D^* have the special form considered in no. 12. The reader may examine whether the method indicated there—the principle of reductions—can be applied here.

Recall the theorem to be proved: if the positive Hermitian form (19) has lower limit $J > 0$, then the corresponding substitution B has an inverse. For a positive numerical constant α , write

$$B = \frac{1}{\alpha}[E - (E - \alpha B)].$$

This gives the formal expansion

$$B^{-1} = \alpha\{E + (E - \alpha B) + (E - \alpha B)^2 + \cdots\}.$$

It remains to choose α so that $M_{E-\alpha B} < 1$. The square of this bound is the upper limit, under (18), of

$$\begin{aligned} \sum_{i=1}^{\infty} \left| x_i - \alpha \sum_{k=1}^{\infty} b_{ik} x_k \right|^2 &= \sum_{i=1}^{\infty} |x_i|^2 - 2\alpha \sum_{i,k=1}^{\infty} b_{ik} x_i \overline{x_k} \\ &\quad + \alpha^2 \sum_{i=1}^{\infty} \left| \sum_{k=1}^{\infty} b_{ik} x_k \right|^2. \end{aligned}$$

Consequently

$$M_{E-\alpha B}^2 \leq 1 - 2\alpha J + \alpha^2 M_B^2,$$

and, since $J > 0$, the right-hand side is less than 1 whenever

$$0 < \alpha < \frac{2J}{M_B^2}.$$

Every such α therefore determines B^{-1} .⁶

64. Let us emphasize once more the fact from which Hilb started and which will be useful later:

Theorem. *If $M_A < 1$, the substitution $E - A$ has an inverse.*

We have seen how Toeplitz's criteria follow from it. Conversely those general criteria include the special hypothesis $M_A < 1$. Indeed, the two Hermitian forms involved are

$$\sum_{i=1}^{\infty} \left| x_i - \sum_{k=1}^{\infty} a_{ik} x_k \right|^2, \quad \sum_{k=1}^{\infty} \left| x_k - \sum_{i=1}^{\infty} a_{ik} x_i \right|^2.$$

⁶A somewhat more exact discussion gives the bound $2/M_B$. The expansion converges for every smaller value of α and ceases to converge for $\alpha = 2/M_B$; convergence is fastest for $\alpha = 2/(J + M_B)$.

The triangle inequality gives

$$\sum_{i=1}^{\infty} \left| x_i - \sum_{k=1}^{\infty} a_{ik} x_k \right|^2 \geq (1 - M_A)^2 \sum_{k=1}^{\infty} |x_k|^2,$$

and the same inequality for the transposed form. Thus Toeplitz's conditions are satisfied when $M_A < 1$; $E - A$ has an inverse and

$$M_{(E-A)^{-1}} \leq \frac{1}{1 - M_A}.$$

Completely Continuous Substitutions

65. We have just obtained criteria for a substitution A to possess an inverse A^{-1} . While these conditions hold, systems (4) and (10) have unique solutions, obtained by applying A^{-1} and $\mathfrak{A}^{-1}$ to the given elements. Up to this point the substitutions behave exactly as if there were only finitely many variables. What happens when the inverse does not exist?

Recall the finite-dimensional result. When the inverse does not exist, each of the homogeneous systems

$$\sum_{k=1}^n a_{ik} x_k = 0 \quad (i = 1, \dots, n), \quad \sum_{i=1}^n a_{ik} x_i = 0 \quad (k = 1, \dots, n)$$

has one or more solutions. If (x_i^0) is a solution of the second, then the nonhomogeneous system

$$\sum_{k=1}^n a_{ik} x_k = x'_i$$

can have a solution only if

$$\sum_{i=1}^n x'_i x_i^0 = 0.$$

Conversely, if this relation holds for every solution of the transposed homogeneous system, the nonhomogeneous system has solutions; and the two homogeneous systems have the same number of independent solutions.

These simple results fail completely for infinitely many variables. For example, the substitution

$$x'_k = x_{k+1} \quad (k = 1, 2, \dots)$$

has no inverse. Yet its two homogeneous systems are

$$x_k = 0 \quad (k = 2, 3, \dots), \quad x_i = 0 \quad (i = 1, 2, \dots),$$

which are not of the same type: in the first x_1 is arbitrary, whereas the second has only the trivial solution. The substitution $x'_k = x_k/k$ also has no inverse, since an inverse would map $x'_k = 1/k$ to $x_k = 1$, which is not an element of Hilbert space; but both associated homogeneous systems have only the trivial solution. On the other hand, the two homogeneous systems corresponding to $x'_k = x_1/k$ both have infinitely many independent solutions.

66. There is nevertheless a broad class of substitutions for which the finite-dimensional results remain valid. If, for example, the double series $\sum_{i,k} |a_{ik}|^2$ converges, the substitution $E - A$ has the required behavior, as follows from the method of infinite determinants. This is only a special case of the one we shall study, in which A is assumed *completely continuous*.

Every linear substitution is continuous: ordinary convergence of elements implies ordinary convergence of their transforms, and strong convergence implies strong convergence. A linear substitution A will be called *completely continuous* when it maps every ordinarily convergent sequence $(x_k^{(n)})$ to a sequence $(x_k^{(n)'})$ which converges strongly to the corresponding element (x'_k) .⁷

For very simple examples showing the nature of this restriction, consider

$$x'_k = a_k x_k \quad (k = 1, 2, \dots).$$

These formulas define a bounded, hence continuous, substitution exactly when the a_k are bounded; it is completely continuous exactly when $a_k \rightarrow 0$.

⁷In Hilbert's theory the bilinear form $A(x, y)$ is called completely continuous (*vollstetig*) when

$$(x_k^{(n)}) \rightarrow (x_k), \quad (y_k^{(n)}) \rightarrow (y_k)$$

imply $A(x^{(n)}, y^{(n)}) \rightarrow A(x, y)$. The definition in the text and Hilbert's are related by the following fact. Given (u_k) and a sequence $(u_k^{(n)})$ in Hilbert space, the relation

$$\sum_{k=1}^{\infty} u_k^{(n)} x_k^{(n)} \longrightarrow \sum_{k=1}^{\infty} u_k x_k$$

for every element (x_k) and every sequence $(x_k^{(n)}) \rightarrow (x_k)$ holds if and only if $(u_k^{(n)})$ tends strongly to (u_k) . Compare the remark following formula (28) of [Chapter III](#); the fact stated there proves the sufficiency. This correspondence between completely continuous substitutions and forms also shows that the transpose $\mathfrak{A}$ of a completely continuous substitution is completely continuous.

In particular, E is not completely continuous. It follows directly from the definition that if at least one of A, B is completely continuous, then AB is also. A completely continuous substitution therefore cannot have an inverse, for otherwise $E = AA^{-1}$ would be completely continuous.

If, with the exception of a single row or a single column, all coefficients of A vanish, then A is completely continuous. Sums of finitely many completely continuous substitutions are also completely continuous. Consequently, if some m satisfies $a_{ik} = 0$ whenever both indices exceed m , then A is completely continuous.

67. We shall study the systems corresponding to $E - A$, assuming A completely continuous. This study could be connected with the general arguments of the [preceding chapter](#), especially Schmidt's theory. I prefer to give a special method which is a kind of generalization of the reasoning of [no. 25](#). It seems to have been invented by A. C. Dixon,⁸ who applied it to substitutions on bounded systems (x_k) .⁹ With a slight modification, Dixon's method serves our present substitutions.

Given $A = (a_{ik})$, let R_n be obtained by replacing by zeros all entries in its first n rows and first n columns, and let M_{R_n} be its bound. As n increases these bounds do not increase. Complete continuity implies the much stronger assertion

$$M_{R_n} \longrightarrow 0.$$

Indeed, for each n choose an element $(x_k^{(n)})$ with $x_1^{(n)} = \dots = x_n^{(n)} = 0$ and $\sum_k |x_k^{(n)}|^2 = 1$, for which

$$\sum_{i=n+1}^{\infty} \left| \sum_{k=n+1}^{\infty} a_{ik} x_k^{(n)} \right|^2$$

comes within $1/n$ of its upper bound $M_{R_n}^2$. The sequence $(x_k^{(n)})$ tends ordinarily to zero; therefore its images under A tend strongly to zero:

$$\sum_{i=1}^{\infty} \left| \sum_{k=n+1}^{\infty} a_{ik} x_k^{(n)} \right|^2 \longrightarrow 0.$$

⁸Dixon, *On a class of matrices of infinite order and on the existence of "matricial" functions on a Riemann surface*, received May 15, 1901, *Transactions of the Cambridge Philosophical Society*, vol. 19, pp. 190–233.

⁹Dixon assumes constants α_k such that $|a_{ik}| \leq \alpha_k$ and $\sum_k \alpha_k$ converges. The weaker condition $A_i = \sum_k |a_{ik}| \rightarrow 0$ as $i \rightarrow \infty$ would suffice.

For substitutions acting on bounded systems (x_k) , define convergence by $x_k^{(n)} \rightarrow x_k$ for every k together with a common bound on all $|x_k^{(n)}|$, and strong convergence by uniform convergence in k . Then a matrix defines a linear substitution exactly when $A_i = \sum_k |a_{ik}|$ remains bounded, and it is completely continuous when $A_i \rightarrow 0$.

Together with

$$M_{R_n}^2 \leq \frac{1}{n} + \sum_{i=n+1}^{\infty} \left| \sum_{k=n+1}^{\infty} a_{ik} x_k^{(n)} \right|^2 \leq \frac{1}{n} + \sum_{i=1}^{\infty} \left| \sum_{k=n+1}^{\infty} a_{ik} x_k^{(n)} \right|^2,$$

this proves $M_{R_n} \rightarrow 0$. In particular, for sufficiently large n , $M_{R_n} < 1$. Choose such an n . By [no. 64](#), $E - R_n$ then has an inverse; write

$$(E - R_n)^{-1} = E + B.$$

The first n rows and first n columns of (b_{ik}) consist entirely of zeros.

68. For simplicity decompose

$$A = A_n + P_n + Q_n + R_n,$$

where A_n has the coefficients of A for $i \leq n, k \leq n$; P_n those for $i \leq n, k > n$; and Q_n those for $i > n, k \leq n$, all remaining coefficients being zero. Let E_n be the projection $x'_k = x_k$ for $k \leq n$, $x'_k = 0$ for $k > n$. Multiplying $E = (E + B)(E - R_n)$ by P_n gives

$$P_n = P_n(E + B)(E - R_n).$$

Adding $E_n - A_n - P_n - P_n(E + B)Q_n$ to both sides yields

$$E_n - A_n - P_n(E + B)Q_n = E_n - A_n - P_n + P_n(E + B)(E - Q_n - R_n). \quad (22)$$

Let $(x'_k) = (E - A)(x_k)$. Applied to (x_k) , the right-hand side of (22) gives the same result as $E_n + P_n(E + B)$ applied to (x'_k) . Put

$$C = E_n - A_n - P_n(E + B)Q_n, \quad D = E_n + P_n(E + B).$$

Then $C(x_k) = D(x'_k)$. The substitution C may be regarded as one in n variables, since its coefficients vanish if $i > n$ or $k > n$.

This symbolic computation reduces the infinite system

$$x_i - \sum_{k=1}^{\infty} a_{ik} x_k = x'_i \quad (i = 1, 2, \dots) \quad (23)$$

to one involving only $x_1, \dots, x_n$. Indeed, set aside the first n equations and write the others as

$$x_i - \sum_{k=n+1}^{\infty} a_{ik} x_k = x'_i + \sum_{k=1}^n a_{ik} x_k \quad (i = n+1, n+2, \dots).$$

Solving for $x_{n+1}, x_{n+2}, \dots$ gives

$$x_i = x'_i + \sum_{k=1}^n a_{ik}x_k + \sum_{j=n+1}^{\infty} b_{ij} \left(x'_j + \sum_{k=1}^n a_{jk}x_k \right).$$

Substitution in the equations set aside eliminates the remaining infinite tail and gives

$$\sum_{k=1}^n c_{ik}x_k = \sum_{j=1}^{\infty} d_{ij}x'_j \quad (i = 1, 2, \dots, n), \quad (24)$$

where c_{ik} and d_{ij} are the coefficients of C and D .

An analogous process transforms the transposed system

$$x_k - \sum_{i=1}^{\infty} a_{ik}x_i = x''_k \quad (25)$$

into

$$\sum_{i=1}^n c_{ik}x_i = \sum_{j=1}^{\infty} d'_{jk}x''_j \quad (k = 1, 2, \dots, n). \quad (26)$$

The d'_{jk} , coefficients of $E_n + (E + B)Q_n$, will not concern us for the moment. The important point is that the coefficients on the left are the same as in (24), since they form the transpose of C . Thus the study of the infinite systems (23) and (25) is reduced to that of the finite systems (24) and (26).

69. Two cases must be distinguished.

First case. The determinant $|c_{ik}|_n$ does not vanish. Then the finite substitution C_n has an inverse C_n^{-1} , regarded also as an infinite substitution by filling missing coefficients with zeros. Applying $C_n^{-1}D$ to (x'_i) yields the true values of $x_1, \dots, x_n$ and zeros for the remaining coordinates. Substituting those first n values in the preceding expression for the tail shows that

$$E - E_n + B + Q_n C_n^{-1}D + BQ_n C_n^{-1}D$$

gives the true values of $x_{n+1}, x_{n+2}, \dots$ and zeros for the first n coordinates. Hence

$$E - E_n + B + C_n^{-1}D + Q_n C_n^{-1}D + BQ_n C_n^{-1}D$$

gives the solution of (23); equivalently,

$$(E - A)(E - E_n + B + C_n^{-1}D + Q_n C_n^{-1}D + BQ_n C_n^{-1}D) = E. \quad (27)$$

An analogous argument for (25) supplies a right inverse of $E - A$. The two one-sided inverses must coincide; therefore the substitution displayed in (27) is $(E - A)^{-1}$.

Second case. The determinant $|c_{ik}|_n$ vanishes.

Then the two finite homogeneous systems

$$\sum_{k=1}^n c_{ik}x_k = 0 \quad (i = 1, \dots, n), \quad \sum_{i=1}^n c_{ik}x_i = 0 \quad (k = 1, \dots, n) \quad (28)$$

have the same number m of independent solutions. Denote bases for the first and second systems by

$$(\alpha_1^{(1)}, \dots, \alpha_n^{(1)}), \dots, (\alpha_1^{(m)}, \dots, \alpha_n^{(m)})$$

and

$$(\beta_1^{(1)}, \dots, \beta_n^{(1)}), \dots, (\beta_1^{(m)}, \dots, \beta_n^{(m)}).$$

Pass to the infinite homogeneous systems obtained from (23) and (25) by putting the given element equal to zero. The first n coordinates of any solution form a solution of the corresponding finite system (28). Conversely, every solution of either finite system extends uniquely to a solution of the corresponding infinite system. For example, for the homogeneous system (23), the remaining unknowns satisfy

$$x_i - \sum_{k=n+1}^{\infty} a_{ik}x_k = \sum_{k=1}^n a_{ik}x_k^0 \quad (i = n+1, n+2, \dots),$$

and are obtained by applying $(E + B)Q_n$ to $(x_1^0, \dots, x_n^0, 0, 0, \dots)$. Thus every infinite homogeneous solution is obtained by applying

$$E_n + (E + B)Q_n$$

to a corresponding finite solution. This is precisely the substitution whose matrix is (d'_{ik}) ; hence the general infinite solution is

$$x_i^0 = \sum_{k=1}^n d'_{ik}x_k^0 \quad (i = 1, 2, \dots).$$

Applying this process to the m solutions α gives m linearly independent solutions $(\alpha_k^{(j)})$ ($j = 1, \dots, m$) of the infinite homogeneous system (23), and every solution is their linear combination. The same statement holds, with the same number m , for the homogeneous system (25) and the extended β solutions.

Now consider the nonhomogeneous systems, say (25). Reduction to (26) is always possible. The finite system (26) is solvable if and only if

$$\sum_{k=1}^n \left(\sum_{j=1}^{\infty} d'_{jk} x''_j \right) x_k^0 = 0$$

for every solution $(x_1^0, \dots, x_n^0)$ of the first homogeneous system (28). Equivalently,

$$\sum_{j=1}^{\infty} x''_j \left(\sum_{k=1}^n d'_{jk} x_k^0 \right) = \sum_{j=1}^{\infty} x''_j x_j^0 = 0.$$

But (x_j^0) is the general solution of the infinite homogeneous system (23). Thus (25) is solvable precisely when

$$\sum_{k=1}^{\infty} x''_k x_k^0 = 0$$

for every solution (x_k^0) of the homogeneous system (23). Whenever (x''_k) is so chosen, (25) has several solutions; the general solution is obtained from any particular solution by adding an arbitrary linear combination of the m elements $(\beta_k^{(j)})$. Analogous results hold for the nonhomogeneous system (23).

In summary:

Theorem. *If A is completely continuous, the infinite systems (23) and (25) retain the essential properties of finite systems containing the same number of equations and unknowns.*

Observe that complete continuity was used only to infer that $M_{R_n} < 1$ for all sufficiently large n . All the preceding conclusions remain valid if this last property alone is assumed.

70. The preceding considerations also permit a variable parameter λ to be introduced and the inverse $(E - \lambda A)^{-1}$ to be studied as a function of it. Suppose λ varies in the disk $|\lambda| \leq r$. For completely continuous A , choose n so that $M_{R_n} < 1/r$. Then $E - \lambda R_n$ has, for every such λ , an inverse $E + B(\lambda)$; the coefficients of $B(\lambda)$ are holomorphic in the disk. The same is true of the coefficients of the corresponding substitutions $C(\lambda)$, $C_n(\lambda)$, and $D(\lambda)$.

The inverse $C_n^{-1}(\lambda)$ is computed by finite determinants, which are holomorphic functions. Since a nonzero holomorphic function has only finitely many zeros in a

bounded closed domain, $C_n^{-1}(\lambda)$ exists except possibly at finitely many values. If it fails at λ_0 , it can be written

$$C_n^{-1}(\lambda) = \frac{G(\lambda)}{(\lambda - \lambda_0)^m},$$

with the coefficients of G holomorphic at λ_0 . Finally,

$$\begin{aligned} (E - \lambda A)^{-1} &= E - E_n + B(\lambda) + C_n^{-1}(\lambda)D(\lambda) \\ &\quad + \lambda Q_n C_n^{-1}(\lambda)D(\lambda) + \lambda B(\lambda)Q_n C_n^{-1}(\lambda)D(\lambda). \end{aligned}$$

This proves the same assertions for $(E - \lambda A)^{-1}$: in brief, the inverse is a meromorphic function of λ . The conclusion holds for all λ , since the radius r may be chosen arbitrarily.

In cases amenable to infinite determinants—for example when $\sum_{i,k} |a_{ik}|^2$ converges—the result follows immediately from the fact that the infinite determinant with entries $e_{ik} - \lambda a_{ik}$ is holomorphic in λ .

Sequences and Series of Substitutions

71. In [no. 63](#), while explaining Hilb's method, we said that the series

$$E + A + A^2 + \dots$$

converges, when $M_A < 1$, to $(E - A)^{-1}$; but we neither proved the assertion nor specified its meaning. We shall fill this gap and at the same time develop a few general facts about sequences of substitutions. The arguments extend immediately to other limiting processes depending, for example, on a continuous parameter rather than an integer index.

Let (A_n) be an infinite sequence of linear substitutions, and let $(a_{ik}^{(n)})$ be their matrices. Suppose:

1. all bounds M_{A_n} are below one finite number M ;
2. for every i, k , $a_{ik}^{(n)} \rightarrow a_{ik}$ as $n \rightarrow \infty$.

Then the a_{ik} are the coefficients of a linear substitution A such that

$$M_A \leq M. \tag{29}$$

Indeed, for every choice of the integers l, m and the quantities $x_1, \dots, x_m$,

$$\sum_{i=1}^l \left| \sum_{k=1}^m a_{ik} x_k \right|^2 = \lim_{n \rightarrow \infty} \sum_{i=1}^l \left| \sum_{k=1}^m a_{ik}^{(n)} x_k \right|^2 \leq M^2 \sum_{k=1}^m |x_k|^2.$$

By no. 56, this is precisely the condition for (a_{ik}) to define a substitution A satisfying (29).

Let (x_k) now be arbitrary, and let $(x_k^{(n)'})$ and (x'_k) be the elements obtained by applying A_n and A , respectively. Hypothesis 1 gives, for every i, n ,

$$\sum_{k=1}^{\infty} |a_{ik}^{(n)}|^2 \leq M^2,$$

and therefore, by no. 40,

$$x_i^{(n)'} = \sum_{k=1}^{\infty} a_{ik}^{(n)} x_k \longrightarrow \sum_{k=1}^{\infty} a_{ik} x_k = x'_i.$$

Moreover, all sums $\sum_k |x_k^{(n)'}|^2$ remain at most $M^2 \sum_k |x_k|^2$. Thus $(x_k^{(n)'})$ tends ordinarily to (x'_k) , whatever the initial element (x_k) . Under these hypotheses we shall say that the substitutions A_n *tend to* A .

72. Series (21) belongs to a still more special type. Given an infinite sequence (A_n) , we shall say that it tends *uniformly* to A when

$$M_{A-A_n} \longrightarrow 0.$$

The two hypotheses of no. 71 then hold, since

$$M_{A_n} \leq M_A + M_{A-A_n}, \quad |a_{ik} - a_{ik}^{(n)}| \leq M_{A-A_n}.$$

Consequently A_n tends to A also in the earlier sense. In particular, $A_n(x_k)$ tends ordinarily to $A(x_k)$. More is true:

$$\sum_{k=1}^{\infty} |x'_k - x_k^{(n)'}|^2 \leq M_{A-A_n}^2 \sum_{k=1}^{\infty} |x_k|^2,$$

so the convergence is strong, and is uniform throughout every bounded domain of Hilbert space (that is, every domain on which $\sum_k |x_k|^2 \leq G^2$).

Uniform convergence has the further remarkable property

$$M_{A_n} \longrightarrow M_A,$$

which follows immediately from

$$|M_A - M_{A_n}| \leq M_{A-A_n}.$$

We now ask: given a sequence (A_n) , how can one determine whether there exists a substitution A to which it converges uniformly? A necessary condition follows from

$$M_{A_n - A_m} \leq M_{A - A_n} + M_{A - A_m};$$

namely,

$$M_{A_n - A_m} \longrightarrow 0 \quad \text{as } m, n \rightarrow \infty \text{ independently.} \quad (30)$$

This condition is also sufficient. For if it holds, then

$$|M_{A_n} - M_{A_m}| \leq M_{A_n - A_m}, \quad |a_{ik}^{(n)} - a_{ik}^{(m)}| \leq M_{A_n - A_m}$$

show that M_{A_n} and every $a_{ik}^{(n)}$ have limits M and a_{ik} . Thus the hypotheses of [no. 71](#) hold and (a_{ik}) defines a substitution A to which A_n tends. Likewise, for fixed m , $A_n - A_m$ tends to $A - A_m$. Given $\varepsilon > 0$, choose m so large that $M_{A_n - A_m} < \varepsilon$ for every $n > m$. By [\(29\)](#), $M_{A - A_m} \leq \varepsilon$, and hence $M_{A - A_m} \rightarrow 0$.

Theorem. *The sequence (A_n) converges uniformly if and only if $M_{A_n - A_m} \rightarrow 0$ as $m, n \rightarrow \infty$ independently.*

73. For the partial sums of [\(21\)](#) this condition is fulfilled. Put $S_n = E + A + \cdots + A^{n-1}$ and suppose $n > m$.^m Then

$$S_n - S_m = A^m + A^{m+1} + \cdots + A^{n-1},$$

and

$$M_{S_n - S_m} \leq (M_A)^m + \cdots + (M_A)^{n-1} = \frac{(M_A)^m - (M_A)^n}{1 - M_A}.$$

If $M_A < 1$, this tends to zero; hence S_n converges uniformly to a substitution S .

The following theorem, which follows immediately from

$$M_{BA - BA_n} \leq M_B M_{A - A_n}, \quad M_{AB - A_n B} \leq M_{A - A_n} M_B,$$

shows that $S = (E - A)^{-1}$.

Theorem. *If A_n converges uniformly to A^* and B is any linear substitution, then BA_n and $A_n B$ converge uniformly to BA^* and $A^* B$.*

^mTranslator's note: The French text reverses the two terms in the numerator of the final fraction below. Their order is corrected so that the estimate is positive for $n > m$ and $M_A < 1$.

Apply this with $A_n = S_n$, $A^* = S$, and $B = E - A$. Since

$$(E - A)S_n = S_n(E - A) = E - A^n \longrightarrow E,$$

we obtain

$$(E - A)S = S(E - A) = E, \quad S = (E - A)^{-1}.$$

74. We record the more general proposition:

Theorem. *If A_n and B_n converge uniformly to A and B , respectively, then $A_n B_n$ converges uniformly to AB .*

Indeed,

$$M_{AB-A_n B_n} \leq M_A M_{B-B_n} + M_{A-A_n} M_{B_n},$$

while $M_{A-A_n} \rightarrow 0$, $M_{B-B_n} \rightarrow 0$, and $M_{B_n} \rightarrow M_B$.

The analogous proposition for nonuniform convergence is false. For example, let

$$A_n : x'_1 = x_n, \quad x'_i = 0 \ (i > 1), \quad B_n : x'_n = x_1, \quad x'_i = 0 \ (i \neq n).$$

Both A_n and B_n tend to substitutions all of whose coefficients vanish. Yet every product $A_n B_n$ is the same substitution

$$C : x'_1 = x_1, \quad x'_i = 0 \ (i > 1),$$

so $A_n B_n = C \rightarrow C$, and C is not identically zero.

For completeness we add an easily proved result:

Theorem. *If $A_n \rightarrow A$ and $B_n \rightarrow B$ and at least one of the two sequences converges uniformly, then $A_n B_n \rightarrow AB$.¹⁰*

75. There is another important case in which $A_n B_n \rightarrow AB$. The simplest sequences tending to A are its reductions: in (a_{ik}) set equal to zero every entry for which at least one index exceeds n . In general these reductions do not converge uniformly to A ; that occurs only when A is completely continuous. But the reductions possess an essential special property. Formula (3) shows that their successive application to any element (x_k) produces elements tending strongly to (x'_k) . We therefore insert between convergence and uniform convergence the notion of *strong convergence*. If $A_n \rightarrow A$, we shall say that A_n tends strongly to A when, for every (x_k) , the elements $A_n(x_k)$ tend strongly to $A(x_k)$.

¹⁰This includes the corollary: if $A_n \rightarrow A$ and B is any fixed linear substitution, then $A_n B \rightarrow AB$ and $BA_n \rightarrow BA$.

Theorem. If A_n and B_n tend strongly to A and B , respectively, then $A_n B_n$ tends strongly to AB .

The bounds M_{A_n} and M_{B_n} remain bounded, and therefore so do the bounds of $A_n B_n$. It remains only to show that $[AB - A_n B_n](x_k)$ tends strongly to zero. Write

$$AB - A_n B_n = (A - A_n)B + A_n(B - B_n).$$

For the first term, B maps (x_k) to some (y_k) and $(A - A_n)(y_k)$ tends strongly to zero. For the second, put

$$(B - B_n)(x_k) = (y_k^{(n)}), \quad A_n(y_k^{(n)}) = (z_k^{(n)}).$$

By hypothesis $(y_k^{(n)})$ tends strongly to zero, and

$$\sum_k |z_k^{(n)}|^2 \leq M_{A_n}^2 \sum_k |y_k^{(n)}|^2;$$

hence $(z_k^{(n)})$ also tends strongly to zero.

In particular, if A_n is the n th reduction of A , then for every fixed k the powers A_n^k tend strongly to A^k .

76. Suppose A_n tends uniformly to A and each A_n has an inverse. Can we infer the existence of A^{-1} , and, if so, is it the limit of A_n^{-1} ? This question is closely connected with the principle of reductions.

First suppose the bounds $M_{A_n^{-1}}$ remain bounded. Then A_n^{-1} converges uniformly and its limit is A^{-1} . Indeed,

$$A_n^{-1} - A_m^{-1} = A_n^{-1}(A_m - A_n)A_m^{-1},$$

so

$$M_{A_n^{-1} - A_m^{-1}} \leq M_{A_n^{-1}} M_{A_m^{-1}} M_{A_n - A_m} \longrightarrow 0.$$

Let the uniform limit be A^* . Since $A_n \rightarrow A$ and $A_n^{-1} \rightarrow A^*$, the products $A_n A_n^{-1}$ and $A_n^{-1} A_n$ tend uniformly to AA^* and A^*A ; but both products equal E . Thus $AA^* = A^*A = E$, and $A^* = A^{-1}$.

Conversely, suppose A^{-1} exists and only that $A_n \rightarrow A$ uniformly. Then A_n^{-1} exists for all sufficiently large n , namely whenever

$$M_{A - A_n} < \frac{1}{M_{A^{-1}}}.$$

For in that case

$$M_{E-A^{-1}A_n} = M_{A^{-1}(A-A_n)} \leq M_{A^{-1}}M_{A-A_n} < 1,$$

so $A^{-1}A_n$ has an inverse B . From $BA^{-1}A_n = E$ and $A^{-1}A_nB = E$, multiplication of the second equality on the left by A and on the right by A^{-1} gives $A_nBA^{-1} = E$; hence $BA^{-1} = A_n^{-1}$. Moreover,

$$\begin{aligned} M_{A_n^{-1}} &\leq M_B M_{A^{-1}} \\ &\leq \frac{M_{A^{-1}}}{1 - M_{A^{-1}}M_{A-A_n}}, \end{aligned}$$

which tends to $M_{A^{-1}}$. Thus the inverses exist eventually, their bounds remain collectively bounded, and the preceding result gives $A_n^{-1} \rightarrow A^{-1}$ uniformly.

Theorem. *Let A_n converge uniformly to A . The inverse A^{-1} exists if and only if, from some index onward, the inverses A_n^{-1} exist and their bounds remain collectively bounded; in that case A_n^{-1} converges uniformly to A^{-1} .*

The essential point of the argument, needed later, is this:

Theorem. *If A^{-1} exists and $M_B < 1/M_{A^{-1}}$, then $(A + B)^{-1}$ also exists.*

This is a generalization of [no. 64](#).

77. These results justify the principle of reductions in an important case. We have said that the reductions A_n of A do not in general converge uniformly to A ; but if A is completely continuous, they do.¹¹ Therefore $E - A_n$ converges uniformly to $E - A$. If $(E - A)^{-1}$ exists, then from some index onward $(E - A_n)^{-1}$ exists and converges uniformly to $(E - A)^{-1}$. Thus, for completely continuous A , whenever $(E - A)^{-1}$ exists its calculation may be based on the principle of reductions.

Study of the Inverse $(E - \lambda A)^{-1}$ as a Function of λ

78. Let λ be a complex parameter and study $E - \lambda A$ from the standpoint of inversion. One advantage of this study is that it presents within a single object the

¹¹The converse is also true: if $M_{A-A_n} \rightarrow 0$, then A is completely continuous. This is contained in the more general proposition that a uniform limit of completely continuous substitutions is completely continuous. It also covers the condition $M_{R_n} \rightarrow 0$ of [no. 67](#). Indeed, $A_n + P_n + Q_n$ is always completely continuous, and $M_{R_n} \rightarrow 0$ says that these substitutions converge uniformly to A . Consequently, together with [no. 67](#), $M_{R_n} \rightarrow 0$ is a necessary and sufficient condition for complete continuity of A .

ⁿ*Translator's note:* In this footnote the French original prints $A_n - P_n + Q_n$ instead of $A_n + P_n + Q_n$, and concludes with B instead of A ; both misprints are corrected above.

two principal cases. In general there are two classes of values of λ : for some, $E - \lambda A$ has an inverse; for the others it does not. We call the first values *ordinary* and the second *singular*. These terms, borrowed from function theory, are justified by the relations between that theory and the study of $(E - \lambda A)^{-1}$. In studying completely continuous substitutions we already touched this problem and observed facts concerning the analytic nature of the inverse.

Some arguments below also apply to the inverse of

$$E - \sum_{k=1}^n \lambda^k A_k,$$

or to other substitutions depending upon λ by less simple laws. We restrict ourselves to $E - \lambda A$.

79. Let A be any linear substitution and consider $(E - \lambda A)^{-1}$ at ordinary values of λ . It is convenient to introduce A_λ by

$$(E - \lambda A)^{-1} = E + \lambda A_\lambda. \quad (31)$$

For every ordinary $\lambda \neq 0$ this determines A_λ uniquely; set $A_0 = A$, which, as we shall see, defines it by continuity. Equation (31) is equivalent to

$$E - \lambda A = (E + \lambda A_\lambda)^{-1}. \quad (32)$$

Let λ and μ be ordinary values. From (32),

$$(\mu - \lambda)E = \mu(E + \lambda A_\lambda)^{-1} - \lambda(E + \mu A_\mu)^{-1}.$$

Multiplying on the left by $E + \lambda A_\lambda$ and on the right by $E + \mu A_\mu$ gives

$$(\mu - \lambda)(E + \lambda A_\lambda)(E + \mu A_\mu) = \mu(E + \mu A_\mu) - \lambda(E + \lambda A_\lambda),$$

or

$$\lambda\mu [A_\lambda - A_\mu + (\mu - \lambda)A_\lambda A_\mu] = 0.$$

If $\lambda\mu \neq 0$, it follows that

$$A_\lambda - A_\mu + (\mu - \lambda)A_\lambda A_\mu = 0. \quad (33)$$

Interchanging λ and μ gives

$$A_\lambda - A_\mu + (\mu - \lambda)A_\mu A_\lambda = 0. \quad (34)$$

Thus multiplication of A_λ and A_μ is commutative.

Equations (33) and (34) remain valid when $\lambda\mu = 0$. If, for example, $\mu = 0$, they say

$$A - A_\lambda + \lambda AA_\lambda = A - A_\lambda + \lambda A_\lambda A = 0.$$

Indeed, writing (32) more explicitly gives

$$(E - \lambda A)(E + \lambda A_\lambda) = (E + \lambda A_\lambda)(E - \lambda A) = E, \quad (35)$$

and hence

$$-\lambda(A - A_\lambda + \lambda AA_\lambda) = -\lambda(A - A_\lambda + \lambda A_\lambda A) = 0.$$

Division by $-\lambda$ is legitimate if $\lambda \neq 0$; the case $\lambda = \mu = 0$ is evident. Thus (33) and (34) hold in all cases.

80. Let ordinary values $\lambda_1, \lambda_2, \dots$ tend to λ^* , and suppose all $M_{A_{\lambda_n}}$ are below a number M . Either resolvent identity gives

$$M_{A_{\lambda_n} - A_{\lambda_m}} \leq |\lambda_n - \lambda_m| M^2.$$

Hence A_{λ_n} converges uniformly to a substitution A^* . Then $E + \lambda_n A_{\lambda_n}$ converges uniformly to $E + \lambda^* A^*$. The two product sequences in (35) converge to

$$(E - \lambda^* A)(E + \lambda^* A^*), \quad (E + \lambda^* A^*)(E - \lambda^* A),$$

respectively. Since every term equals E , both limits equal E . Therefore λ^* is ordinary and $E + \lambda^* A^*$ is the inverse of $E - \lambda^* A$.

Theorem. *The limiting value λ^* is ordinary, and $M_{A_{\lambda^*} - A_{\lambda_n}} \rightarrow 0$.*

On the entire set of ordinary values, M_{A_λ} is a continuous function of λ . From (33) and the inequalities for bounds,

$$|M_{A_\lambda} - M_{A_\mu}| \leq |\lambda - \mu| M_{A_\lambda} M_{A_\mu}.$$

When both bounds are nonzero this yields

$$\left| \frac{1}{M_{A_\lambda}} - \frac{1}{M_{A_\mu}} \right| \leq |\lambda - \mu|.$$

Thus $1/M_{A_\lambda}$, and hence M_{A_λ} , is continuous wherever the latter is nonzero. But A_λ can vanish identically only if $A = 0$, by $A = A_\lambda + \lambda AA_\lambda$. Consequently M_{A_λ} is continuous throughout the set of ordinary values.

81. The set of ordinary values is open. Indeed, if μ is ordinary, every λ satisfying

$$|\lambda - \mu| < \frac{1}{M_{A_\mu}}$$

is ordinary. For

$$\begin{aligned} E - \lambda A &= E - \mu A - (\lambda - \mu)A \\ &= E - \mu A - (\lambda - \mu)(E - \mu A)(E + \mu A_\mu)A \\ &= E - \mu A - (\lambda - \mu)(E - \mu A)A_\mu \\ &= (E - \mu A)[E - (\lambda - \mu)A_\mu]. \end{aligned}$$

The first factor is invertible by hypothesis, and the second because $|\lambda - \mu|M_{A_\mu} < 1$. Its inverse is the uniformly convergent series

$$E + (\lambda - \mu)A_\mu + (\lambda - \mu)^2 A_\mu^2 + \cdots .$$

Multiplication gives

$$(E - \lambda A)^{-1} = E + \lambda A_\mu + \lambda(\lambda - \mu)A_\mu^2 + \lambda(\lambda - \mu)^2 A_\mu^3 + \cdots ,$$

and therefore

$$A_\lambda = A_\mu + (\lambda - \mu)A_\mu^2 + (\lambda - \mu)^2 A_\mu^3 + \cdots .$$

Equivalently,

$$\frac{A_\lambda^k - A_\mu^k}{\lambda - \mu} \longrightarrow kA_\mu^{k+1} \quad (\lambda \rightarrow \mu)$$

uniformly. Thus A_μ , as a function of μ , has successive derivatives

$$A_\mu^2, \quad 2A_\mu^3, \quad \dots, \quad k!A_\mu^{k+1}, \quad \dots$$

In short, for ordinary λ , A_λ and the other substitutions entering the calculation have the character of holomorphic functions of λ .

82. One may proceed further by applying the methods of function theory to A_λ , especially the calculus of residues. We merely indicate some results.

Let D be a domain bounded by finitely many closed curves, which may be assumed analytic. The integral along these curves, with respect to λ , of a substitution depending on λ is defined without ambiguity from the definition of convergent sequences of substitutions. If the boundary of D consists of ordinary values, these integrals exist and the whole classical apparatus of Cauchy applies.

Suppose this condition holds and that 0 lies outside D . For any integer k , positive, negative, or zero, define

$$A^{(k)} = -\frac{1}{2\pi i} \oint_{\partial D} \lambda^{-k} A_\lambda d\lambda.$$

Residue calculus applied to (33)–(34) gives

$$AA^{(k)} = A^{(k)}A = A^{(k+1)}, \quad A^{(k)}A^{(l)} = A^{(k+l)}.$$

These relations contain many remarkable consequences. For $k = l = 1$,

$$(A - A^{(1)})A^{(1)} = A^{(1)}(A - A^{(1)}) = 0;$$

thus $A^{(1)}$ and $A - A^{(1)}$ are *orthogonal*. More generally, for any integer k and positive integer l , $A^{(k)}$ and $A^l - A^{(l)}$ are orthogonal.

Multiplying the relations of no. 79 by $A^{(0)}$ and using the identities above gives

$$(E - \lambda A^{(1)})(E + \lambda A^{(0)}A_\lambda) = (E + \lambda A_\lambda A^{(0)})(E - \lambda A^{(1)}) = E.$$

Hence every value ordinary for A is ordinary for $A^{(1)}$, with inverse

$$E + \lambda A^{(0)}A_\lambda = E + \lambda A_\lambda A^{(0)}.$$

An analogous calculation shows that λ is ordinary for $A - A^{(1)}$ and that the corresponding inverse is

$$E + \lambda A_\lambda - \lambda A^{(0)}A_\lambda = E + \lambda A_\lambda - \lambda A_\lambda A^{(0)}.$$

For brevity put $B = A^{(1)}$ and $C = A - A^{(1)}$, and introduce B_λ and C_λ analogously to A_λ . Then

$$B = A^{(0)}A = AA^{(0)}, \quad C = (E - A^{(0)})A = A(E - A^{(0)}),$$

$$B_\lambda = A^{(0)}A_\lambda = A_\lambda A^{(0)}, \quad C_\lambda = (E - A^{(0)})A_\lambda = A_\lambda(E - A^{(0)}).$$

We already know $BC = CB = 0$, and similarly

$$BC_\lambda = C_\lambda B = B_\lambda C = CB_\lambda = B_\lambda C_\lambda = C_\lambda B_\lambda = 0.$$

Whenever A_λ exists, B_λ and C_λ exist as well. More is true: B_λ exists for every λ outside D , without exception, and C_λ exists for every λ inside D , even when λ is singular for A . Indeed, residue calculus shows that the substitutions

$$\frac{1}{2\pi i} \oint_{\partial D} \frac{A_\mu d\mu}{\lambda - \mu} \quad (\lambda \text{ outside}), \quad \frac{1}{2\pi i} \oint_{\partial D} \frac{A_\mu d\mu}{\mu - \lambda} \quad (\lambda \text{ inside})$$

satisfy the defining equations for B_λ and C_λ , respectively. So extended, they remain orthogonal to C and B .

The importance of the decomposition $A = B + C$ is seen as follows. Let λ be any value inside D , and consider the two infinite systems corresponding to $E - \lambda A$ and $E - \lambda B$, with the same given element (x'_k) . The identities

$$E - \lambda A = (E - \lambda B)(E - \lambda C), \quad E - \lambda B = (E - \lambda A)(E + \lambda C_\lambda)$$

show that applying $E - \lambda C$ to a solution of the first system gives a solution of the second, and applying $E + \lambda C_\lambda$ to a solution of the second gives one of the first. For the homogeneous systems, the relations

$$E - \lambda B = (E + \lambda C_\lambda)(E - \lambda A), \quad E - \lambda A = (E - \lambda C)(E - \lambda B)$$

show that the two systems have exactly the same solutions. These solutions also satisfy the homogeneous system corresponding to $E - A^{(0)}$, since

$$(E - A^{(0)})(E - \lambda B) = E - A^{(0)},$$

or equivalently $B = A^{(0)}B$. The solutions of this last system are exactly the elements obtained by applying $A^{(0)}$ to all of Hilbert space, since $A^{(0)} = A^{(0)}A^{(0)}$. Call them the *principal elements* corresponding to D . Thus, for an interior λ , the solutions of the homogeneous system corresponding to $E - \lambda A$ lie among the principal elements.

The principal elements have another remarkable property: restricted to their set, A defines a one-to-one correspondence. They are of the form $A^{(0)}(x_k)$, and since $AA^{(0)} = A^{(0)}A$, their images are of the same form. Moreover, on this set $A^{(-1)}$ is an inverse of A , because

$$A^{(-1)}AA^{(0)} = A^{(0)}, \quad AA^{(-1)}A^{(0)} = A^{(0)}.$$

We leave this somewhat too general train of ideas, while observing that the interesting questions it raises are far from exhausted, and add only a few words about completely continuous A . Sums of completely continuous substitutions, and products having at least one completely continuous factor, are completely continuous; the relations above therefore show successively that A_λ , $A^{(k)}$, B_λ , and C_λ are completely continuous. In this special case the singular values are isolated, by [no. 70](#). If λ_0 is singular, choose D to be a small circle about it. Then B_λ exists for every $\lambda \neq \lambda_0$. The substitution $A^{(0)}$, applied to all of Hilbert space, gives the principal elements corresponding to λ_0 . But $A^{(0)}$ is completely continuous.

If a completely continuous substitution is applied to Hilbert space, the resulting elements can be expressed as linear combinations of finitely many of them. Thus the study of the one-to-one correspondence defined by A on the set of principal elements—and hence the study of A_λ in a neighborhood of λ_0 —reduces to that of a linear substitution in a finite number of variables and is completed by the classical methods of the theory of linear substitutions.

The same arguments apply also to the transpose $\mathfrak{A}$ of A , and the substitutions $\mathfrak{A}_\lambda, \mathfrak{A}^{(k)}, \mathfrak{B}_\lambda, \mathfrak{C}_\lambda$ thereby obtained are the transposes of the substitutions $A_\lambda, A^{(k)}, B_\lambda, C_\lambda$ which we have just considered.

The method I have just sketched is not confined to the theory presently under discussion. A reader versed in the theory of integral equations will have recognized from the very beginning the parallelism between our arguments and certain more or less recent investigations belonging to that theory.¹² This parallelism is immediately explained by observing that the two theories, that of integral equations and that of linear substitutions in infinitely many variables, are special cases of a much more general theory, namely the theory of distributive operations.¹³

¹²Cf., for example, E. Goursat, "Recherches sur les équations intégrales linéaires," *Annales de la Faculté des Sciences de Toulouse*, vol. X (1908), pp. 5–98.

¹³Cf. on this subject S. Pincherle's article in the *Encyclopédie des Sciences mathématiques*, vol. II, part 5, fascicle 1.

Chapter V.

The Theory of Quadratic Forms in Infinitely Many Variables

Generalities. Quadratic Forms in a Finite Number of Variables

83. In the [preceding chapter](#) we considered, among other things, matrices (a_{ik}) such that $a_{ik} = \overline{a_{ki}}$. The corresponding substitutions displayed certain special properties which became apparent on studying the Hermitian form

$$\sum_{i,k=1}^{\infty} a_{ik} x_i \overline{x_k}.$$

But it was always the general theory of linear substitutions that we had in view, and our special matrices played only an auxiliary role in it. In what follows we shall confine ourselves to such matrices. To simplify the statements, we shall further suppose the a_{ik} real,¹ and consequently $a_{ik} = a_{ki}$; this will lead us to consider the real quadratic forms in infinitely many variables

$$\sum_{i,k=1}^{\infty} a_{ik} x_i x_k.$$

The results we shall obtain extend almost immediately to Hermitian forms and to the matrices and substitutions corresponding to them.

84. Our point of departure will be certain well-known facts concerning quadratic forms in a finite number of variables. All these facts are contained, in germ, in the following fundamental theorem.²

¹Throughout this chapter, the quantities in question will in general be real. The contrary hypothesis will always be stated expressly.

²Cauchy, *Exercices de Mathématiques*, fourth year; Paris, 1829, p. 159.

Theorem. *Every quadratic form in n variables*

$$A(x, x) = \sum_{i,k=1}^n a_{ik} x_i x_k, \quad a_{ik} = a_{ki}, \quad (1)$$

can be decomposed into n squares of linear forms,

$$A(x, x) = \sum_{j=1}^n \mu_j \left(\sum_{k=1}^n l_{jk} x_k \right)^2, \quad (2)$$

and this can be done in such a way that

$$\sum_{j=1}^n \left(\sum_{k=1}^n l_{jk} x_k \right)^2 = \sum_{k=1}^n x_k^2. \quad (3)$$

Here is the most important consequence of this theorem. Let A denote the substitution in n variables corresponding to the matrix (a_{ik}) , and let E denote the identity substitution in n variables. Consider the quadratic form

$$\sum_{j=1}^n \frac{\left(\sum_{k=1}^n l_{jk} x_k \right)^2}{\lambda - \mu_j}. \quad (4)$$

It is well defined for every value of λ , except the values $\lambda = \mu_j$. The linear substitution corresponding to it is precisely the inverse of $\lambda E - A$.³

Indeed, formulas (2) and (3) may be interpreted as follows. Let E_j be the substitution corresponding to the quadratic form $\left(\sum_{k=1}^n l_{jk} x_k \right)^2$. Since, by (3), the matrix (l_{jk}) is orthogonal and normalized, we plainly have $E_j^2 = E_j$ and $E_i E_j = 0$ for $i \neq j$; moreover, $E_1 + E_2 + \cdots + E_n = E$. By (2),

$$A = \mu_1 E_1 + \cdots + \mu_n E_n,$$

and hence

$$\lambda E - A = (\lambda - \mu_1) E_1 + \cdots + (\lambda - \mu_n) E_n.$$

On the other hand, the substitution corresponding to the quadratic form (4) is

$$\frac{E_1}{\lambda - \mu_1} + \cdots + \frac{E_n}{\lambda - \mu_n}.$$

³Considering $\lambda E - A$, instead of $E - \lambda A$, amounts to replacing λ by $1/\lambda$. This modification is not essential; it merely conforms better to the order of ideas we shall follow. Among other things, it has the advantage that $\lambda = \infty$ becomes an ordinary value.

The product of these two substitutions, which plainly commute, is $E_1 + \cdots + E_n = E$. They are therefore inverses of one another.

This argument does not suppose λ real. Thus (4) gives the expression for $(\lambda E - A)^{-1}$, or more precisely for the corresponding quadratic form, for every ordinary value of the complex parameter λ . It also exhibits the singular values $\lambda = \mu_1, \mu_2, \dots, \mu_n$, and at the same time shows how the substitution $(\lambda E - A)^{-1}$ behaves in a neighborhood of those singular values.

In short, in the case of finitely many variables, the decomposition (2) of the form (1) gives at once the solution of every problem concerning the inverse of $\lambda E - A$. Will the same be true for infinitely many variables? Yes. In the memoir already mentioned many times, Hilbert proved that every real bounded quadratic form in infinitely many variables can be decomposed in a manner analogous to (2) and (3); only, in general, finite sums must be replaced by two kinds of infinite processes. On the one hand, one must sum a countable infinity of terms analogous to those in (2) and (3); on the other, one must integrate with respect to a continuous parameter. I observed elsewhere that these two procedures may be united by using the notion of the Stieltjes integral, and that this way of stating Hilbert's theorem offers some advantages for the proof.⁴

85. Before passing finally to quadratic forms in infinitely many variables, let us return once more to the form (1) and to the corresponding substitution A . Let $A^2, A^3, \dots$ be the powers of this substitution. In view of the formulas

$$E_i E_j = \begin{cases} E_i, & i = j, \\ 0, & i \neq j, \end{cases}$$

the corresponding quadratic forms are plainly

$$\sum_{j=1}^n \mu_j^2 \left(\sum_{k=1}^n l_{jk} x_k \right)^2, \quad \sum_{j=1}^n \mu_j^3 \left(\sum_{k=1}^n l_{jk} x_k \right)^2, \quad \dots$$

Let, further, $v_0, v_1, \dots, v_r$ be arbitrary real numbers, and set $v_0 + v_1 \mu + \cdots + v_r \mu^r = f(\mu)$. Consider the substitution $v_0 E + v_1 A + \cdots + v_r A^r$, which, by an obvious symbolic notation, may be denoted by $f(A)$. The corresponding quadratic form is

$$\sum_{j=1}^n f(\mu_j) \left(\sum_{k=1}^n l_{jk} x_k \right)^2. \quad (5)$$

⁴See my letter to Hilbert, "Ueber quadratische Formen von unendlich vielen Veränderlichen," *Nachrichten der Gesellschaft der Wissenschaften zu Göttingen* (1910), pp. 190–195.

By (3), the value of this expression is a certain mean of the values $f(\mu_1), \dots, f(\mu_n)$, multiplied by $\sum_{k=1}^n x_k^2$. On the other hand, the smallest and largest of the quantities μ_j are respectively equal to the minimum m and maximum M of the form (1), varied subject to $\sum_{k=1}^n x_k^2 = 1$; this follows immediately from our decomposition formulas. Consequently, *the set of values of the form (5), varied under the same condition, lies entirely between the two extreme values of $f(\mu)$ on the interval $[m, M]$.*^o

Quadratic Forms in Infinitely Many Variables. Symbolic Sequences and Products

86. Let (a_{ik}) be a doubly indexed matrix, real and symmetric in i and k . Consider the quadratic form

$$A(x, x) = \sum_{i,k=1}^{\infty} a_{ik} x_i x_k \quad (6)$$

and its sections

$$[A(x, x)]_n = \sum_{i,k=1}^n a_{ik} x_i x_k.$$

I assume that there exists a positive number M such that

$$|[A(x, x)]_n| \leq M \sum_{k=1}^n x_k^2,$$

whatever n and the x_k may be. When this hypothesis is satisfied, we say, with Hilbert, that the form (6) is *bounded*.⁵

Associate with the quadratic form (6) the bilinear form

$$A(x, y) = \sum_{i,k=1}^{\infty} a_{ik} x_i y_k$$

^oTranslator's note: The French source uses (m, M) , here and throughout this chapter, for an interval including its endpoints. Modern bracket notation is used in the translation.

⁵It should be observed that, in presenting his investigations, Hilbert begins from the most general possible point of view. Without making any assumption on the orders of magnitude of the coefficients a_{ik} , he regards the form (6) as a symbol for the collection of its sections. Cf. also the note by J. Le Roux, "Sur les formes quadratiques définies à une infinité de variables," *Comptes rendus*, January 10, 1910, whose point of view is less general but more accessible to calculation.

and its sections

$$[A(x, y)]_n = \sum_{i,k=1}^n a_{ik} x_i y_k.$$

Plainly,

$$\begin{aligned} 4|[A(x, y)]_n| &= |[A(x + y, x + y)]_n - [A(x - y, x - y)]_n| \\ &\leq M \left[\sum_{k=1}^n (x_k + y_k)^2 + \sum_{k=1}^n (x_k - y_k)^2 \right] \\ &= 2M \sum_{k=1}^n (x_k^2 + y_k^2). \end{aligned}$$

Consequently, when $\sum_{k=1}^n x_k^2 \leq 1$ and $\sum_{k=1}^n y_k^2 \leq 1$, we also have

$$|[A(x, y)]_n| \leq M.$$

Hence, by homogeneity, in the general case,

$$|[A(x, y)]_n| \leq M \left(\sum_{k=1}^n x_k^2 \sum_{i=1}^n y_i^2 \right)^{1/2}.$$

Put, in particular,

$$y_k = \sum_{i=1}^n a_{ik} x_i;$$

then

$$\sum_{i=1}^n \left(\sum_{k=1}^n a_{ik} x_k \right)^2 \leq M^2 \sum_{k=1}^n x_k^2.$$

That is, under the hypothesis made, the matrix (a_{ik}) corresponds to a linear substitution A , and $M_A \leq M$. It also follows, by [no. 58](#), that for every element (x_k) of Hilbert space the doubly indexed series (6) converges to a determinate limit, independent of the manner in which the limit is taken. In particular,

$$[A(x, x)]_n \longrightarrow A(x, x).$$

Conversely, let A be a linear substitution in infinitely many variables, with coefficients a_{ik} real and symmetric in i and k . Let M_A be the bound of A . By definition,

$$\sum_{i=1}^{\infty} \left(\sum_{k=1}^n a_{ik} x_k \right)^2 \leq M_A^2 \sum_{k=1}^n x_k^2,$$

and the Cauchy–Lagrange inequality gives

$$|[A(x, x)]_n| \leq \left[\sum_{i=1}^n \left(\sum_{k=1}^n a_{ik} x_k \right)^2 \right]^{1/2} \left(\sum_{k=1}^n x_k^2 \right)^{1/2} \leq M_A \sum_{k=1}^n x_k^2.$$

Thus the form (6) is bounded.

In summary, for a given real symmetric matrix (a_{ik}) , the following two hypotheses are equivalent: (1) it corresponds to a bounded quadratic form $A(x, x)$; (2) it corresponds to a linear substitution A . The bound M_A of the substitution is at the same time the upper bound of $|A(x, x)|$, varied subject to $\sum_{k=1}^{\infty} x_k^2 = 1$.

87. Consider now a sequence $A_1, A_2, \dots$ of bounded quadratic forms, and suppose that the corresponding substitutions tend to a substitution A (no. 71). Under these conditions, by no. 40, we shall also have

$$A_n(x, y) \longrightarrow A(x, y), \quad (7)$$

and in particular

$$A_n(x, x) \longrightarrow A(x, x).$$

Conversely, we may suppose that this last relation holds for every element (x_k) . Then, a fortiori, the sections, and hence the coefficients, of the forms A_n also converge to those of A . Consequently, if the quantities $M_{A_1}, M_{A_2}, \dots$ are also bounded as a whole, we may assert that *the substitutions $A_1, A_2, \dots$ converge to the substitution A .*

Let $A(x, x)$ and $B(x, x)$ be two bounded quadratic forms, and let A and B be their corresponding substitutions. Their product AB need not correspond to a quadratic form, since its coefficient matrix need not be symmetric in i and k . It is symmetric if and only if $AB = BA$. In that case we shall call the quadratic form

$$AB(x, x) = BA(x, x) = \sum_{i=1}^{\infty} \left(\sum_{k=1}^{\infty} a_{ik} x_k \right) \left(\sum_{k=1}^{\infty} b_{ik} x_k \right)$$

the *symbolic product* of the forms A and B .

We shall need the following fact: if

$$A_n(x, x) \longrightarrow A(x, x)$$

and, moreover, the quantities $M_{A_1}, M_{A_2}, \dots$ are bounded as a whole, then

$$A_n B(x, x) \longrightarrow AB(x, x). \quad (8)$$

This fact could be connected with the arguments of nos. 71 and following; it also follows from (7) on setting $(y_k) = B(x_k)$.

Symbolic Functions of a Quadratic Form. The Correspondence Between Functions of One Variable and Symbolic Functions

88. Let A be a linear substitution that is both real and symmetric. Its powers $A^2, A^3, \dots$ will have the same properties, as will the polynomials $f(A) = v_0E + v_1A + \dots + v_rA^r$.

Each of the substitutions $E, A, A^2, \dots, f(A)$ corresponds to a bounded quadratic form $E(x, x), A(x, x), A^2(x, x), \dots, f(A)(x, x)$. For brevity we shall speak of the quadratic forms $E, A, A^2, \dots, f(A)$.

Let A_n be the n -th section of the substitution A ; it may be regarded either as a substitution in infinitely many variables or as a substitution in n variables. It corresponds to a quadratic form in n variables which is simply the n -th section of the form $A(x, x)$. Likewise the powers $A_n^2, A_n^3, \dots$ and the polynomials $f(A_n)$ each give a quadratic form in n variables: $A_n^2(x, x), A_n^3(x, x), \dots, f(A_n)(x, x)$. By [no. 75](#), for every element (x_k) ,

$$f(A_n)(x, x) \longrightarrow f(A)(x, x). \quad (9)$$

This relation enables us to extend the theorem of [no. 85](#) to quadratic forms in infinitely many variables. Indeed, let m_n and M_n be the minimum and maximum of the form A_n , varied subject to $E_n = \sum_{k=1}^n x_k^2 = 1$; they plainly lie between the lower bound m and upper bound M of the form A , varied subject to $E = 1$. By the theorem to be extended, as μ ranges from m_n to M_n , $f(A_n)(x, x)$ lies between the extreme values of $f(\mu)E_n(x, x)$. Passing to the limit and using (9), we see that:

The set of values of the form $f(A)$, varied subject to $E = 1$, lies between the two extreme values of $f(\mu)$, with μ ranging over the interval $[m, M]$.

In particular, if $f(\mu) > 0$ throughout the interval $[m, M]$, then $f(A)$ is a positive quadratic form.

89. We have just made a uniquely determined quadratic form $f(A)$ correspond to each polynomial $f(\mu)$. This correspondence has the following properties:

- I. It is *distributive*: if $\varphi = c_1f_1 + c_2f_2$, then $\varphi(A) = c_1f_1(A) + c_2f_2(A)$.
- II. The set of values of $f(A)$, when $E = 1$, lies between the extreme values of $f(\mu)$.
- III. It is *multiplicative*: the ordinary product of two functions f_1, f_2 corresponds to the symbolic product of the forms $f_1(A), f_2(A)$.

We shall see that the correspondence may be extended to a much wider field of functions in such a way that all three stated properties remain valid.

The passage from polynomials to continuous functions is immediate. By the well-known theorem of Weierstrass, every function continuous on $[m, M]$ can be uniformly approximated there by a sequence of polynomials. Every such sequence corresponds to a sequence of quadratic forms; by what precedes, this sequence also converges uniformly. It therefore has a limiting form, which we make correspond to the given continuous function. It is at once clear that the limiting form does not depend on the particular sequence chosen to approximate the given function. It is equally easy to see that the stated properties remain valid for the correspondence so established.

For the arguments that follow, however, continuous functions are not enough. We shall extend the correspondence to a field containing, in addition to continuous functions, certain discontinuous functions. It is clear that to do so we must relinquish the exclusive use of uniformly convergent sequences.⁶

90. Consider a sequence of polynomials $[f_n(\mu)]$. Suppose that $f_1(\mu) \leq f_2(\mu) \leq f_3(\mu) \leq \dots$ on the interval $[m, M]$; we express this by saying that the sequence is increasing. Suppose also that it is bounded. Then the sequence tends on $[m, M]$ to a bounded function $f(\mu)$. On the other hand, by I and II, the forms $f_n(A)$ also constitute an increasing bounded sequence; they remain $\leq E$ times the upper bound of $f(\mu)$. Consequently, the $f_n(A)$ tend to a limiting form, which also remains $\leq E$ times that upper bound.

Let us denote the limiting form by $f(A)$ and attach it to the function $f(\mu)$. To justify this convention we must prove that the limiting form depends only on the limiting function. More explicitly, when two increasing sequences of polynomials $[f_n(\mu)]$, $[g_n(\mu)]$ tend to the same limiting function, we must prove that the forms $f_n(A)$, $g_n(A)$ also tend to the same limiting form.

The fact to be proved is contained in the following slightly more comprehensive result. Let $[f_n(\mu)]$, $[g_n(\mu)]$ be two increasing sequences, with limiting functions $f(\mu)$ and $g(\mu)$, and suppose moreover that $f(\mu) \leq g(\mu)$. I assert that $f(A) \leq g(A)$. Indeed, let $f_m(\mu)$ be any polynomial in the first sequence and let $\varepsilon > 0$ be arbitrary. Hold m and ε fixed and run through the sequence $[g_n(\mu)]$. For sufficiently large n

⁶The analogous idea of considering the correspondence between functions of one or several variables and symbolic functions of certain functional operations was recently applied successfully by V. Volterra to the study of integral equations and of a mixed type of functional equations (integro-differential equations), in a series of notes published in the *Atti della Reale Accademia dei Lincei*. See also the same author's *Leçons sur les équations intégrales et les équations intégro-différentielles*, recently published in this Collection. It should be observed, however, that Volterra confines himself to analytic functions; here, on the contrary, discontinuous functions are essential.

we shall have $g_n(\mu) > f_m(\mu) - \varepsilon$. Otherwise, the values μ satisfying

$$f_m(\mu) - \varepsilon \geq g_1(\mu), \quad f_m(\mu) - \varepsilon \geq g_2(\mu), \quad \dots$$

would form a sequence of closed sets, each containing those that follow, and at least one point μ^* would belong to all of them. Then $f(\mu^*) > f_m(\mu^*) - \varepsilon \geq g(\mu^*)$, contrary to the hypothesis. Thus for all sufficiently large n , $f_m - \varepsilon < g_n$, and therefore $f_m(A) - \varepsilon E < g_n(A)$. This implies $f_m(A) - \varepsilon E < g(A)$, and since m and ε are arbitrary, $f(A) \leq g(A)$, as was to be proved.

The fact that the limiting form depends only on the limiting function is the case $f = g$; it follows from the result just established by replacing the equality $f = g$ by the two inequalities $f \leq g$ and $g \leq f$.

Thus the correspondence between $f(\mu)$ and $f(A)$, first established for polynomials, extends uniquely to every bounded function that is the limit of an increasing sequence of polynomials. Plainly it may also be extended to limits of decreasing sequences; one need only change signs. There is more. Let f and g be two functions of the type just studied. Then $h = f + g$ is of the same type and plainly $h(A) = f(A) + g(A)$. In contrast, $\varphi = f - g$ will in general be neither of the same nor of the opposite type. Define $\varphi(A) = f(A) - g(A)$. To justify this convention, we must show that if $f - g = f^* - g^*$, then also

$$f(A) - g(A) = f^*(A) - g^*(A).$$

The hypothesis may be written $f + g^* = f^* + g$; both sides now belong to the type just studied. Therefore

$$f(A) + g^*(A) = f^*(A) + g(A),$$

and consequently

$$f(A) - g(A) = f^*(A) - g^*(A).$$

The convention is legitimate, and our correspondence is thus extended to functions of the type $f - g$.

The extended correspondence still has properties I, II, and III. First, it is plainly distributive. It also has property II: *the set of values of the form $\varphi(A) = f(A) - g(A)$, for $E(x, x) = 1$, lies between the lower and upper bounds of $\varphi(\mu)$* . For example, if c is the lower bound, then $f(\mu) \geq g(\mu) + c$, and hence $f(A) \geq g(A) + cE$, that is, $\varphi(A) \geq cE$. The argument for the upper bound is the same.

Finally, the extended correspondence also has property III: it is *multiplicative*. Without loss of generality it suffices to prove this for two functions $f(\mu)$, $g(\mu)$

which are the limits of two increasing sequences of polynomials $[f_n(\mu)]$, $[g_n(\mu)]$. We may moreover suppose that f, g, f_n, g_n are positive, which amounts to adding suitable constants.

91. Consider the sequence of functions $[f(\mu)g_n(\mu)]$; it increases to the function $f(\mu)g(\mu)$. Since all these functions are limits of increasing sequences of polynomials, there correspond to them uniquely determined forms, which we denote by $f g_n(A)$ and $f g(A)$. I assert that

$$f g_n(A) \longrightarrow f g(A). \quad (9)$$

Indeed, let $p(\mu)$ be any polynomial with $p(\mu) < f(\mu)g(\mu)$. The points where $f_m(\mu)g_n(\mu) \leq p(\mu)$ form a closed set $F_{m,n}$. The set F_n of points where $f(\mu)g_n(\mu) \leq p(\mu)$, being the limiting set of the closed sets $F_{1,n}, F_{2,n}, \dots$, each of which contains the following ones, is also closed. Finally, each of the closed sets $F_1, F_2, \dots$ contains those that follow; hence from some rank onward the sets F_n must be empty. Otherwise they would have at least one common point μ^* , and we would have $f(\mu^*)g(\mu^*) \leq p(\mu^*)$, contrary to the hypothesis. Thus for sufficiently large n , $f(\mu)g_n(\mu) > p(\mu)$, whence $f g_n(A) \geq p(A)$, and consequently

$$\lim_{n \rightarrow \infty} f g_n(A) \geq p(A). \quad (10)$$

Let $[p_n(\mu)]$ now be an increasing sequence of polynomials tending to $f g$ (for example, $p_n = f_n g_n$). The preceding argument applies to all polynomials $p_n(\mu) - 1/n$, and hence

$$\lim_{n \rightarrow \infty} f g_n(A) \geq \lim_{n \rightarrow \infty} \left[p_n(A) - \frac{1}{n} E \right] = f g(A). \quad (11)$$

On the other hand, for every n , $f g_n(\mu) \leq f g(\mu)$, and consequently $f g_n(A) \leq f g(A)$; hence

$$\lim_{n \rightarrow \infty} f g_n(A) \leq f g(A). \quad (12)$$

Comparing (11) and (12) gives the asserted result (9).

With this result established, the argument is soon completed. Since the correspondence is multiplicative for polynomials,

$$f_m(A)g_n(A) = f_m g_n(A),$$

and therefore, by (8),

$$f(A)g_n(A) = f g_n(A).$$

The same formula (8) gives

$$f(A)g_n(A) \longrightarrow f(A)g(A).$$

Consequently,

$$f g_n(A) \longrightarrow f(A)g(A).$$

Comparison with (9) yields

$$f g(A) = f(A)g(A),$$

that is, the correspondence is multiplicative.

Let us add one observation that will be used later. The argument by which we established (9) also implies the more general proposition: *if a sequence of functions of type f (that is, bounded functions that are limits of increasing sequences of polynomials) increases to a function of the same type, the corresponding forms tend to the form corresponding to the limiting function.*

92. It would remain to characterize the enlarged field of functions more precisely. How can one decide whether a given function belongs to it? We need not dwell on this interesting question, which is closely connected with the study of the so-called semicontinuous functions. For the applications that follow, a few observations suffice. I assert that our field contains: (1) all continuous functions; (2) all bounded functions that are limits of increasing or decreasing sequences of continuous functions. The first are simultaneously of type f and type $-f$; limits of increasing sequences are of type f , and limits of decreasing sequences are of type $-f$. Indeed, let $f(\mu)$ be continuous, and choose a polynomial $p_n(\mu)$ which approximates $f(\mu) - 2^{-n}$ to within 2^{-n-2} . Then $[p_n(\mu)]$ increases to $f(\mu)$. If a function is the limit of an increasing sequence of continuous functions $f_n(\mu)$, choose $p_n(\mu)$ so that it approximates the continuous function $f_n(\mu) - 2^{-n}$ to within 2^{-n-2} .

Application of the Correspondence to the Calculation of $(\lambda E - A)^{-1}$ and to the Study of the Spectrum

93. The correspondence between the functions $f(\mu)$ and the quadratic forms $f(A)$ which we have just established immediately supplies the inverse of $\lambda E - A$, and also other related quadratic forms called *spectral forms*.

Indeed, let λ be a real number outside the interval $[m, M]$. The function $f(\mu) = 1/(\lambda - \mu)$ is continuous on $[m, M]$, and hence a form $f(A)$ corresponds to

it. The function $g(\mu) = \lambda - \mu$ corresponds to the form $\lambda E - A$, and the product $f(\mu)g(\mu) = 1$ corresponds to the form E . Consequently,

$$f(A)(\lambda E - A) = (\lambda E - A)f(A) = E;$$

that is, the substitution $f(A)$ is the inverse of $\lambda E - A$.

For complex λ , separate in f and g the real from the purely imaginary parts. If $f_1(\mu) + i f_2(\mu)$ is the decomposition of $f(\mu) = 1/(\lambda - \mu)$, define $f(A) = f_1(A) + i f_2(A)$. The substitution so defined is the inverse of $\lambda E - A$.

In summary, the correspondence between continuous functions $f(\mu)$ and forms $f(A)$ implies the existence of an inverse $(\lambda E - A)^{-1}$ for every value of λ , except possibly the real values between m and M . Moreover, every sequence of continuous functions $f_n(\mu)$ tending to $1/(\lambda - \mu)$ uniformly, or in such a way that $\sum |f_{n+1}(\mu) - f_n(\mu)|$ is bounded, furnishes a procedure for calculating $(\lambda E - A)^{-1}$. Thus, in particular, for sufficiently large $|\lambda|$,

$$(\lambda E - A)^{-1} = \frac{1}{\lambda}E + \frac{1}{\lambda^2}A + \frac{1}{\lambda^3}A^2 + \cdots,$$

in accordance with [no. 73](#).

94. The use of discontinuous functions will enable us to carry the study of our correspondence farther. Let $f(\mu)$ be continuous on the interval $[m, M]$, endpoints included. We may suppose it defined from $-\infty$ to $+\infty$, completing the definition, for example, by putting $f(\mu) = f(m)$ for $\mu < m$ and $f(\mu) = f(M)$ for $\mu > M$. One could remain within $[m, M]$, but the notation would then have certain disadvantages. In any event it would suffice to use, in place of $(-\infty, +\infty)$, a finite interval $[m - \varepsilon, M + \varepsilon]$, where $\varepsilon > 0$ is arbitrary. For definiteness we shall use $(-\infty, +\infty)$.

Partition $(-\infty, +\infty)$ into partial intervals I_k , with k ranging from $-\infty$ to $+\infty$, so that the oscillation of $f(\mu)$ on each interval is at most ω . Let μ_k be an arbitrary point of I_k . Define the discontinuous function f' by setting $f' = f(\mu_k)$ in the interior and at the left endpoint ξ_k of I_k , for every k . Since f' is the difference of two functions, each of which is the limit of an increasing sequence of continuous functions, the extended correspondence attaches to it a uniquely determined form $f'(A)$.^P Introduce also the functions $f_\xi(\mu)$, one for each point ξ , defined

^P*Translator's note:* The French original says that f' itself is the limit of an increasing sequence of continuous functions. That need not hold at an upward jump; the difference-of-two statement is the one justified by the preceding extension of the correspondence.

by $f_\xi(\mu) = 1$ for $\mu < \xi$, and $f_\xi(\mu) = 0$ for $\mu \geq \xi$. To simplify the notation put $f_\xi(A) = A_\xi$. For $\xi \leq m$, $A_\xi = 0$; for $\xi > M$, $A_\xi = E$.

Plainly,

$$f'(\mu) = \sum_k f(\mu_k)[f_{\xi_{k+1}}(\mu) - f_{\xi_k}(\mu)],$$

and consequently

$$f'(A) = \sum_k f(\mu_k)(A_{\xi_{k+1}} - A_{\xi_k}). \quad (13)$$

Since $f - f'$ lies between $-\omega$ and ω , the form $f(A) - f'(A)$ lies between $-\omega E$ and ωE . Thus, in calculating $f'(A)$, we have also calculated $f(A)$ to within ωE . In other words, the right-hand side of (13) is an approximation to $f(A)$, with error at most ωE . Now ω may be made arbitrarily small by choosing the lengths of the intervals I_k sufficiently small. Passing to the limit gives

$$f(A) = \int_{-\infty}^{+\infty} f(\xi) dA_\xi. \quad (14)$$

By this last symbol we mean the limit of (13) as $\omega \rightarrow 0$. It is not an integral in the ordinary sense, but the manner in which it has just been defined is entirely analogous to Riemann's classical definition. The form $A_\xi(x, x)$ is regarded as a function of the parameter ξ , and our integral (14) is of the type $\int f(\xi) d\alpha(\xi)$, first considered by Stieltjes in his celebrated memoir *Recherches sur les fonctions discontinues*.⁷

A few remarks will suffice to show the nature of the Stieltjes integral. If $\alpha(\xi) = \xi$ between a and b , and is constant elsewhere, we recover $\int_a^b f(\xi) d\xi$. If $f(\xi)$ and $\alpha(\xi)$ are continuous and α has a derivative $\alpha'(\xi)$ of which it is an indefinite integral, then $\int f(\xi) d\alpha(\xi)$ immediately becomes $\int f(\xi)\alpha'(\xi) d\xi$. The great advantage of Stieltjes's notion is that it also applies to functions $\alpha(\xi)$ that are not indefinite integrals, and even accommodates certain discontinuous functions. For example, given a countable infinity of distinct values ξ_k and corresponding values a_k such that $\sum |a_k|$ converges, define

$$\alpha(\xi) = \sum a_k,$$

where the sum extends over all k such that $\xi_k < \xi$. Under this hypothesis the integral

$$\int_{-\infty}^{\infty} f(\xi) d\alpha(\xi)$$

⁷Académie des Sciences: *Mémoires présentés par divers savants*, vol. XXXII, no. 2; *Annales de la Faculté des Sciences de Toulouse*, vol. VIII (1894), pp. 1–122; vol. IX (1895), pp. 1–47.

exists for every continuous bounded function $f(\xi)$, and equals

$$\sum_k a_k f(\xi_k).$$

95. Return to formula (14). It gives the analytic expression, analogous to (5), for every form $f(A)$ corresponding to a continuous function $f(\mu)$.⁸⁹ In particular, putting $f(\mu) = 1/(\lambda - \mu)$, we obtain

$$(\lambda E - A)^{-1} = \int_{-\infty}^{\infty} \frac{dA_{\xi}}{\lambda - \xi}. \quad (15)$$

This formula applies to every value of λ , except perhaps real values. By means of the convention we shall now make, it also applies to every real ordinary value, that is, every value for which the inverse $(\lambda E - A)^{-1}$ exists. In the approximating expression (13) for the integral (14), agree to omit terms for which $A_{\xi_{k+1}} - A_{\xi_k}$ vanishes. For functions $f(\mu)$ which do not become infinite, the meaning of the integral is unchanged. With this convention, it is first easy to see that (15) applies for every λ outside $[m, M]$: near $\xi = \lambda$, A_{ξ} remains constant. I assert that (15) holds for every ordinary value of λ . Suppose, indeed, that the nondecreasing function A_{ξ} does not remain constant on any interval containing λ ; in particular it will not be constant on $I = (\lambda - h, \lambda + h)$. Put $f(\mu) = 1$ in the interior and at the left endpoint of I , and zero elsewhere. Plainly $f^2(\mu) = f(\mu)$, and hence $f(A)f(A) = f(A)$. By hypothesis, the nonnegative form $f(A) = A_{\lambda+h} - A_{\lambda-h}$ does not vanish identically; that is, it is positive for at least one system (x_k) . Let (y_k) be the system obtained from (x_k) by applying the substitution $f(A)$. Then $E(y, y) = f(A)(x, x) > 0$, so $(y_k) \neq (0)$. Moreover, applying $f(A)$ to (y_k) reproduces it. Thus applying $(\lambda E - A)^2$

⁸It should be observed here that the correspondence under consideration belongs to the class of linear operations whose analytic expression as limits of integrals was given by J. Hadamard, "Sur les opérations fonctionnelles," *Comptes rendus*, February 9, 1903, and which I succeeded in expressing by a single integral by using the Stieltjes integral, "Sur les opérations fonctionnelles linéaires," *Comptes rendus*, November 29, 1909. Cf. also the more detailed memoir, "Sur certains systèmes singuliers d'équations intégrales," *Annales de l'École Normale* (1911), pp. 33–62, and, in particular for the correspondence considered here, my note cited on p. 124.

Formula (14) could easily be extended to forms corresponding to discontinuous functions; one need only modify Stieltjes's definition to a greater or lesser extent. Cf. also H. Lebesgue, "Sur les intégrales de Stieltjes et les opérations fonctionnelles linéaires," *Comptes rendus*, January 12, 1910.

⁹Translator's note: The French original prints pp. 31–62 for Riesz's "Sur certains systèmes singuliers d'équations intégrales"; the article begins on p. 33.

to (y_k) is equivalent to applying $(\lambda E - A)^2 f(A)$. The latter substitution corresponds to the function $g(\mu) = (\lambda - \mu)^2 f(\mu)$, whose values lie between zero and h^2 . Hence, if (y'_k) denotes what (y_k) becomes after applying $\lambda E - A$, then

$$\frac{\sum_{k=1}^{\infty} y'_k{}^2}{\sum_{k=1}^{\infty} y_k^2} = \frac{(\lambda E - A)^2(y, y)}{\sum_{k=1}^{\infty} y_k^2} \leq \frac{h^2 E(y, y)}{\sum_{k=1}^{\infty} y_k^2} = h^2. \quad (16)$$

But h^2 may be chosen arbitrarily small; under the hypothesis made there is always a corresponding system (y_k) . Thus, by a suitable choice of (y_k) , the left-hand side of (16) can be made arbitrarily small. Consequently, under this hypothesis $\lambda E - A$ has no inverse; the value λ is singular.

Following Hilbert, call the *spectrum* of the form A the set of values λ such that A_ξ remains constant on no interval $(\lambda - h, \lambda + h)$. The result just established may then be stated as follows: *the points of the spectrum represent singular values for the substitution A ; for every other value of λ , the inverse $(\lambda E - A)^{-1}$ exists and is given by the integral (15). In particular, when $\lambda = 0$ does not belong to the spectrum, A^{-1} exists and*

$$A^{-1} = \int_{-\infty}^{\infty} \frac{dA_\xi}{\xi}.$$

The spectrum is contained in the closed interval $[m, M]$. Moreover, *the two endpoints m and M always belong to the spectrum*. Indeed, by its definition the spectrum is a closed set; let m' and M' be its two endpoints. The form A_ξ , regarded as a function of ξ , is constant for $\xi < m'$ and for $\xi > M'$; therefore in (14) we may replace the limits of integration by $m' - \varepsilon$ and $M' + \varepsilon$, where $\varepsilon > 0$ is arbitrary. Applied to the functions $f(\xi) = 1$ and $f(\xi) = \xi$, the modified formula gives

$$\int_{m'-\varepsilon}^{M'+\varepsilon} dA_\xi = E, \quad \int_{m'-\varepsilon}^{M'+\varepsilon} \xi dA_\xi = A.$$

Since A_ξ is monotone, these formulas imply

$$m'E \leq A \leq M'E.$$

Thus $m' \leq m$ and $M' \geq M$. But there are no singular values outside $[m, M]$; consequently $m' = m$ and $M' = M$.

96. To carry the study of the spectrum farther, introduce alongside A_ξ another form $P_\xi(x, x)$, likewise depending on the parameter ξ . For each fixed ξ , this means the form corresponding to the function $f_\xi(\mu) = 0$ for $\mu \neq \xi$ and $f_\xi(\mu) = 1$ for $\mu = \xi$. By II, $P_\xi \geq 0$; and by I and II, for every finite number of distinct points $\xi_1, \dots, \xi_n$,

$P_{\xi_1} + P_{\xi_2} + \cdots + P_{\xi_n} \leq E$. It follows readily that the set of points ξ for which P_ξ does not vanish identically is, if it exists, finite or countable. This set is called the *point spectrum* of the form A .

Here are some further properties of P_ξ which follow immediately from its definition. The relation $f_\xi^2 = f_\xi$ gives $P_\xi^2 = P_\xi$, and for $\xi_1 \neq \xi_2$, the relation $f_{\xi_1}f_{\xi_2} = 0$ gives $P_{\xi_1}P_{\xi_2} = 0$. The relations $f_\xi\mu = \mu f_\xi = \xi f_\xi$ give $P_\xi A = AP_\xi = \xi P_\xi$.

From the last relation follows the fundamental identity $(\lambda E - A)P_\lambda = 0$. It tells us that every system (y_k) obtained from a system (x_k) by applying P_λ is a solution of the homogeneous system

$$\lambda y_i - \sum_{k=1}^{\infty} a_{ik} y_k = 0 \quad (i = 1, 2, \dots). \quad (17)$$

Suppose now that λ belongs to the point spectrum. In that case, by the definition of the point spectrum, there are systems (x_k) such that

$$E(y, y) = P_\lambda^2(x, x) = P_\lambda(x, x) \neq 0.$$

Consequently, for every value λ belonging to the point spectrum, the homogeneous system (17) has nonzero solutions.

Conversely, suppose that the homogeneous system (17) has a nonzero solution (y_k) , that is, one for which $E(y, y) \neq 0$. By (17), applying the substitution A to (y_k) amounts to multiplying the y_k by λ . Consequently, applying $f(A)$ to (y_k) amounts to multiplying the y_k by $f(\lambda)$. In particular, the substitution P_ξ gives (0) when $\xi \neq \lambda$, whereas for $\xi = \lambda$ it carries (y_k) into itself. Finally, $P_\lambda(y, y) = E(y, y) \neq 0$ by hypothesis; hence λ belongs to the point spectrum. We have therefore proved the following theorem.

Theorem. *The system (17) has a nonzero solution if and only if λ belongs to the point spectrum.*

It should also be observed that the formula $P_{\xi_1}P_{\xi_2} = 0$ for $\xi_1 \neq \xi_2$ implies a result which may equally easily be established more directly: *two solutions of (17) corresponding to two distinct values of λ are orthogonal to one another.*

97. There is a very intimate relation between the forms A_ξ and P_ξ , which we shall now establish. To display it clearly, introduce also the form $A_\xi^\pm(x, x)$; by this we mean the form corresponding to the function $f(\mu) = 1$ for $\mu \leq \xi$ and $f(\mu) = 0$ for $\mu > \xi$. Plainly,

$$P_\xi = A_\xi^\pm - A_\xi.$$

Regard A_ξ and $A_\xi^\pm$ as functions of ξ . They are monotone: as ξ increases, they too increase, or at least do not decrease. Thus the four limits $A_{\xi-0}, A_{\xi+0}, A_{\xi-0}^\pm, A_{\xi+0}^\pm$ exist. Moreover, since $A_\xi^\pm \geq A_\xi$ always, while for $\varepsilon > 0$

$$A_{\xi-\varepsilon}^\pm \leq A_\xi, \quad A_{\xi+\varepsilon} \geq A_\xi^\pm,$$

we have

$$A_{\xi-0} \leq A_{\xi-0}^\pm \leq A_\xi, \quad A_{\xi+0}^\pm \geq A_{\xi+0} \geq A_\xi^\pm.$$

Finally, the proposition stated at the end of [no. 91](#) gives $A_{\xi-0} = A_\xi$ and $A_{\xi+0}^\pm = A_\xi^\pm$. Consequently,

$$A_{\xi-0} = A_{\xi-0}^\pm = A_\xi, \quad A_{\xi+0} = A_{\xi+0}^\pm = A_\xi^\pm.$$

In other words, the forms A_ξ and $A_\xi^\pm$, considered as functions of ξ , are continuous and equal to one another at every ξ which does not belong to the point spectrum. At points ξ of the point spectrum they are distinct and remain continuous only when $P_\xi(x, x) = 0$; in general they undergo there a sudden change equal to $P_\xi(x, x)$.

Let us add, as is almost evident, that in most of the preceding arguments—for example in formula (14)—one may replace A_ξ by $A_\xi^\pm$, or, for symmetry, by $\frac{1}{2}(A_\xi + A_\xi^\pm)$.

98. The preceding considerations allow us, following Hilbert, to decompose the form A into two forms of a more special kind. Except perhaps at the point $\xi = 0$, which will play an exceptional role, one of these forms will have the same point spectrum and the same corresponding forms P_ξ as A ; the point spectrum of the other, if it exists, will reduce to $\xi = 0$.

First make a general observation. Suppose that $A = B + C$, where the forms B and C are orthogonal to one another, that is, $BC = CB = 0$. Under this hypothesis,

$$f(A) = f(B) + f(C) - f(0)E. \quad (18)$$

This equality is evident when $f(\mu)$ is a polynomial; for the other functions under consideration it follows by passage to the limit.

Now put

$$P(x, x) = \sum_{\xi} P_{\xi}(x, x),$$

the sum extending over all ξ , or equivalently over the values ξ which belong to the point spectrum. The forms P_ξ are nonnegative and, for every finite set of distinct points $\xi_1, \dots, \xi_n$, $P_{\xi_1} + \dots + P_{\xi_n} \leq E$; hence the series converges. The relations

$P_\xi^2 = P_\xi$ and $P_{\xi_1}P_{\xi_2} = 0$ for $\xi_1 \neq \xi_2$, after summation, give $PP_\xi = P_\xi P = P_\xi$, and another summation gives $P^2 = P$. Likewise, from $A^n P_\xi = P_\xi A^n = \xi^n P_\xi$, we obtain

$$A^n P = P A^n = \sum_{\xi} \xi^n P_\xi. \quad (19)$$

It follows that

$$AP(A - PA) = (A - AP)PA = APA - AP^2A = APA - APA = 0.$$

Thus, on putting $AP = PA = B$ and $A - B = C$, we have $BC = CB = 0$. The forms B and C are orthogonal, and their sum is A .

Let us calculate $f(B)$ and $f(C)$. I assert that

$$f(B) = \sum_{\xi} f(\xi)P_\xi + f(0)(E - P). \quad (20)$$

Indeed, $B^n = A^n P^n = A^n P$; hence by (19), $B^n = \sum_{\xi} \xi^n P_\xi$. Formula (20) is therefore true when f is a polynomial. Without loss of generality it is enough to extend it to bounded functions f which are sums of series of nonnegative polynomials. Since the forms P_ξ are also nonnegative, this merely amounts to interchanging the order of summation in a double series of nonnegative terms, which is permissible. Thus (20) remains valid for all the functions under consideration.

The expression for $f(C)$ follows from (18) and (20):

$$f(C) = f(A) + f(0)P - \sum_{\xi} f(\xi)P_\xi. \quad (21)$$

Calculate in particular the forms P'_ξ and P''_ξ , analogous to P_ξ , which correspond respectively to B and C . In (20) and (21), put $f(\mu) = 1$ for $\mu = \xi$ and $f(\mu) = 0$ for $\mu \neq \xi$. When $\xi \neq 0$, this gives

$$P'_\xi = P_\xi, \quad P''_\xi = 0.$$

For $\xi = 0$, it gives

$$P'_0 = P_0 + E - P, \quad P''_0 = P.$$

Thus apart from $\xi = 0$, the form B has the same point spectrum and the same corresponding forms as A ; as for C , its point spectrum reduces to the point 0, and the corresponding form is $P = \sum_{\xi} P_\xi$.

99. The importance of the preceding decomposition lies in the fact that, in solving the homogeneous system (17), the form A may be replaced by the more special form B . Conversely, when the totality of solutions of (17) is known, it uniquely determines B . To see this, it is enough to express P_ξ in terms of the solutions corresponding to $\lambda = \xi$. We saw that the totality of these solutions is obtained by applying the substitution P_ξ to the whole Hilbert space. If it is applied only to a countable subset dense everywhere in that space and the resulting systems are orthogonalized,⁹ one obtains a finite or countable sequence of normalized, pairwise orthogonal systems

$$(l_k^{(1)}), (l_k^{(2)}), \dots,$$

which solve (17) and such that every solution can be approximated strongly by them or by their linear combinations.

Consider the form

$$Q(x, x) = \sum_i \left(\sum_{k=1}^{\infty} l_k^{(i)} x_k \right)^2$$

and its corresponding substitution Q . The series in parentheses plainly converge. When only finitely many systems $(l_k^{(i)})$ are involved, the right-hand side therefore has a definite meaning. In that case one sees at once that $Q^2 = Q$, and consequently $(E - Q)^2 = E - Q$. Hence $E(x, x) - Q(x, x)$ is a nonnegative form, so that $Q(x, x) \leq E(x, x)$. It follows immediately that the displayed series converges in every case and remains at most $E(x, x)$.

I assert that $P_\xi = Q$. Each system $(l_k^{(i)})$ is reproduced upon application of P_ξ , since it is a solution of (17); and, because the systems are normalized and pairwise orthogonal, each is likewise reproduced upon application of Q . Thus $P_\xi - Q$, applied to any one of the systems $(l_k^{(i)})$, gives zero. The same is therefore true for every solution of (17), since such a solution can be approximated indefinitely closely by linear combinations of the $(l_k^{(i)})$. Finally, $P_\xi^2 = P_\xi$ and $QP_\xi = Q$, so that $(P_\xi - Q)P_\xi = P_\xi - Q$. Hence applying $P_\xi - Q$ to a system amounts first to applying P_ξ and then $P_\xi - Q$. The first operation gives a solution of (17), and the second

⁹Cf. no. 50. There it was the equations themselves that were orthogonalized; here the solutions are orthogonalized by an entirely analogous procedure. After numbering them, one suppresses those which are linear combinations of their predecessors and numbers them anew; one then adds to each of them a linear combination of those preceding it, chosen so that the modified solution is orthogonal to the preceding ones. Finally one multiplies by suitable constants so that $\sum_{k=1}^{\infty} (l_k^{(i)})^2 = 1$.

gives zero on that solution. Thus $P_\xi - Q$ carries the whole Hilbert space into zero; hence $P_\xi = Q$.

Having decomposed each quadratic form P_ξ in this way into squares of linear forms, formula $B = \sum_\xi \xi P_\xi$ likewise gives a similar decomposition of B : one merely replaces each P_ξ by its corresponding sum Q . Thus the special form B has a decomposition analogous to (2), except that the summation may extend over a countable infinity of squares. In the general case, however, after the part B corresponding to the solutions of (17) has been separated from A , a form C still remains. This form too has a special character: its point spectrum, if it exists, reduces to $\xi = 0$; the form C_ξ is a continuous function of ξ , except perhaps at $\xi = 0$; and therefore, after excluding the point 0 if it is isolated, the spectrum of C is a perfect set. This perfect set is called the *continuous spectrum* of the form A .

100. When A is completely continuous, these results become still simpler. In that case $B = AP$, and hence $C = A - B$, are also completely continuous. I assert that $C = 0$. Indeed, C has no point spectrum except perhaps at $\xi = 0$; hence, for $\xi \neq 0$, the homogeneous system corresponding to $\xi E - C$ has no solution. On the other hand, if a point $\xi \neq 0$ belonged to the spectrum of C , this system could be satisfied with arbitrary accuracy by elements (x_k) for which $E(x, x) = 1$. There would thus exist a sequence $(x_k^{(n)})$ such that $E(x_k^{(n)}, x_k^{(n)}) = 1$ and such that the sequence obtained by applying $\xi E - C$ to these elements tends strongly to (0). From it one could extract a subsequence $(x_k^{(n_j)})$ tending to an element (x_k^*) , and the homogeneous system $\xi E - C = 0$ would have the solution (x_k^*) . Moreover, since C is strongly continuous, $C(x_k^{(n_j)})$ would tend strongly to $C(x_k^*)$, and then $(x_k^{(n_j)})$ would tend strongly to its limit. We would therefore have $E(x^*, x^*) = 1$, so that $\xi E - C = 0$ would possess a nonzero solution. Consequently no point $\xi \neq 0$ belongs to the spectrum, and the form C_ξ , regarded as a function of ξ , must be constant for $\xi < 0$ and also for $\xi > 0$. Thus

$$C = \int_{-\infty}^{+\infty} \xi dC_\xi = 0.$$

Since $C = 0$, we have $A = B$. Consequently $A(x, x)$ has a decomposition analogous to (2):

$$A(x, x) = \sum_{j=1}^{\infty} \mu_j \left(\sum_{k=1}^{\infty} l_{jk} x_k \right)^2, \quad E(x, x) = \sum_{j=1}^{\infty} \left(\sum_{k=1}^{\infty} l_{jk} x_k \right)^2. \quad (22)$$

The linear forms $\sum_k l_{jk} x_k$ are normalized and pairwise orthogonal. The coefficients

μ_j run through the spectrum of A , taking each value ξ in it one or more times. For each such value, the corresponding linear forms are obtained by decomposing P_ξ . In the general case this decomposition may yield infinitely many terms; in the present special case it does not. Here only $\xi = 0$ can yield infinitely many terms; each other value yields only finitely many. Moreover, I assert that $\mu_j \rightarrow 0$, which plainly implies the fact just stated. Indeed, the normalized orthogonal elements (l_{jk}) , $j = 1, 2, \dots$, tend to (0) ; applying A gives the sequence $(\mu_j l_{jk})$. Since A is completely continuous, this sequence tends strongly to (0) , that is, $\mu_j^2 \rightarrow 0$.

In summary, *every completely continuous form $A(x, x)$ has the expansion (22), with $\mu_j \rightarrow 0$.*

It is natural to expect that this result can be established more directly, without using the general theory of the spectrum. Hilbert gave such a proof.¹⁰ Its essential idea rests on the following fact. The completely continuous form $A(x, x)$, varied under the condition $E(x, x) = 1$, attains its maximum M at an element $(l_k^{(1)})$ and its minimum m at an element $(l_k^{(2)})$; these elements satisfy respectively the homogeneous systems $ME - A = 0$ and $mE - A = 0$. Further, if $A(x, x)$ is varied while the (x_k) are also required to be orthogonal to certain elements satisfying systems of the same type $\mu E - A = 0$, the extremal elements satisfy systems of that type as well. This fact permits one to exhaust successively all solutions of the homogeneous systems and thus leads to expression (22).

Von Koch showed that, when $\sum_i |a_{ii}|$ and $\sum_{i,k} a_{ik}^2$ converge, expansion (22) can also be obtained by the method of infinite determinants.¹¹

The Continuous Spectrum and Differential Solutions

101. Let us now study the form C corresponding to the continuous spectrum. For simplicity suppose that $C = A$, that is, suppose that A has no point spectrum. The modifications needed in the general case are almost evident; only the point $\xi = 0$ is involved.

Our hypothesis says that, for no value of λ , does system (17) have solutions (x_k) such that $\sum_k x_k^2$ converges and is nonzero. Hilbert gave a very simple example of such a form:

$$A(x, x) = x_1x_2 + x_2x_3 + x_3x_4 + \cdots . \quad (23)$$

¹⁰Hilbert, fourth memoir, p. 201.

¹¹H. von Koch, "Sur un théorème de M. Hilbert," *Mathematische Annalen*, vol. LXIX (1910), pp. 266–283.

Let us discuss the corresponding systems (17). They are recurrence systems: after choosing λ and x_1 arbitrarily, one can calculate $x_2, x_3, \dots$ successively. Since the Cauchy–Lagrange inequality gives $-E \leq A \leq E$, we need consider only values of λ between -1 and 1 . Following Hellinger, put $\lambda = \cos t$ and $x_1 = c \sin t$. A calculation easily restored gives

$$x_k = c \sin kt \quad (k = 1, 2, \dots).$$

As t and c vary, this formula gives all solutions of (17) for $-1 \leq \lambda \leq 1$. For these solutions, $\sum_k x_k^2$ does not converge. Thus the (x_k) are not admissible solutions from our present point of view, and one might think that our methods do not apply to the study of these singular solutions. But not all is lost.

For example, regard the solution $x_k(\lambda) = \sin(k \arccos \lambda)$ as a function of λ , and let y_k be the integral of $x_k(\lambda)$ with respect to λ over an interval I . Since ky_k remains bounded as $k \rightarrow \infty$, the series $\sum_k y_k^2$ converges. If z_k are analogous quantities corresponding to another interval which does not overlap I , then the elements (y_k) and (z_k) are orthogonal. This follows from an easy calculation; we shall soon see the deeper reasons for it.

When the point spectrum is absent, the analogy between these integrals of singular solutions and the admissible solutions in the other case suggested to Hellinger the idea of basing the study of the continuous spectrum on these integrals, without considering the solutions themselves. Another important reason also compelled him to do so. To explain it, I must first indicate the standpoint adopted by Hilbert and his school in studying the spectrum. The necessary and sufficient condition for two quadratic forms in n variables to be transformable into one another by an orthogonal substitution of the variables is that their singular values and respective multiplicities coincide. What are the corresponding conditions for infinitely many variables? When the theory of quadratic forms is organized around this problem, the facts to be considered are naturally delimited: one confines oneself to facts which persist under every orthogonal substitution of the variables; in short, to the *orthogonal invariants* of the quadratic form.¹² The existence of an

¹²The following observation connects the study of orthogonal invariants with our present line of thought. Let O be a real orthogonal substitution; thus, for its coefficients o_{ik} ,

$$\sum_{k=1}^{\infty} o_{ik} o_{jk} = \sum_{k=1}^{\infty} o_{ki} o_{kj} = \begin{cases} 1, & i = j, \\ 0, & i \neq j. \end{cases}$$

Applying O to Hilbert space replaces the forms A by OAO^{-1} . Plainly $f(OAO^{-1}) = Of(A)O^{-1}$; thus the correspondence between A and $f(A)$ is unchanged.

admissible solution of (17) for a given λ is such an invariant; indeed, admissible solutions correspond under the same substitutions as the forms themselves. This is not so for solutions (x_k) for which $\sum_k x_k^2$ diverges: orthogonal substitutions are not defined on such systems and, in most cases, their definition cannot be extended to them.

Regard, then, x_k as a function of λ , and suppose that the equations (17) may be integrated term by term with respect to λ . Put

$$\rho_k(\xi) = \int_0^\xi x_k(\lambda) d\lambda.$$

Using Stieltjes notation, we obtain

$$\int_{\lambda_1}^{\lambda_2} \xi d\rho_i(\xi) - \sum_{k=1}^{\infty} a_{ik} [\rho_k(\lambda_2) - \rho_k(\lambda_1)] = 0, \quad i = 1, 2, \dots \quad (24)$$

Definition. In Hellinger's terminology, a *differential solution* is a sequence of continuous functions $[\rho_k(\xi)]$ such that $\sum_{k=1}^{\infty} [\rho_k(\xi)]^2$ converges to a continuous function and such that the ρ_k satisfy (24) for every pair λ_1, λ_2 .

To obtain such solutions, apply A_ξ to an arbitrary system (x_k) for which $\sum_k x_k^2$ converges. For every ξ there results a definite system $[\rho_k(\xi)]$. Under our hypothesis on A , the form A_ξ is continuous in ξ , and the functions $\rho_k(\xi)$ are continuous as well. Moreover,

$$\sum_{k=1}^{\infty} [\rho_k(\xi)]^2 = A_\xi^2(x, x) = A_\xi(x, x),$$

which is a continuous function of ξ . Finally,

$$\int_{\lambda_1}^{\lambda_2} \xi dA_\xi = A(A_{\lambda_2} - A_{\lambda_1}).$$

Indeed, both sides equal $f(A)$, where f is the function equal to ξ for $\lambda_1 \leq \xi < \lambda_2$ and zero elsewhere. It follows that the functions ρ_k satisfy (24).

Differential solutions share, *mutatis mutandis*, all the essential properties of admissible solutions of (17); all this amounts to saying that their variation over small intervals behaves approximately like exact solutions of (17). Among other things, they may be used to decompose the form A into simpler parts and to study

the equivalence of two forms with respect to orthogonal substitutions. For all details we refer the reader to the original memoirs.¹³

102. Let us mention one more very interesting class of forms for which all these arguments become much simpler. It includes, among others, form (23).¹⁴

Suppose that the functions $\varphi_1(\mu), \varphi_2(\mu), \dots$, defined on the interval (a, b) , form a normalized orthogonal system, that is,

$$\int_a^b \varphi_i(\mu) \varphi_k(\mu) d\mu = \begin{cases} 1, & i = k, \\ 0, & i \neq k. \end{cases}$$

Suppose further that, for every function $f(\mu)$ which is integrable and whose square is integrable, the integral

$$\int_a^b \left[f(\mu) - \sum_{k=1}^n c_k \varphi_k(\mu) \right]^2 d\mu$$

can be made arbitrarily small by a suitable choice of n and the c_k . This last property is expressed by saying that the system $[\varphi_k(\mu)]$ is *complete*.¹⁵ For a system which is

¹³E. Hellinger, *Die Orthogonalinvarianten quadratischer Formen von unendlich vielen Variablen* (doctoral dissertation), Göttingen, 1907; and "Neue Begründung der Theorie quadratischer Formen von unendlich vielen Veränderlichen," *Journal für die reine und angewandte Mathematik*, vol. CXXXVI (1909), pp. 210–271. Hellinger makes very successful use of a highly interesting notion of generalized integral analogous to Stieltjes's. At first sight the use of these integrals seems indispensable. Very recently H. Hahn discovered their intimate relation to ordinary Lebesgue integrals, in particular to the summable functions with summable squares discussed below; by this discovery he was able to solve completely the problem of equivalence of two quadratic forms. See H. Hahn, "Über die Integrale des Herrn Hellinger und die Orthogonalinvarianten der quadratischen Formen von unendlich vielen Veränderlichen," *Monatshefte für Mathematik und Physik*, vol. XXIII (1912), pp. 161–224.

¹⁴Hilbert, fourth memoir, p. 207. Hilbert treats only the special case $u(\mu) = 1/\mu$. The class studied here is contained in a larger class treated by Hellinger.

¹⁵As an example of a normalized, complete orthogonal system on $(-\pi, \pi)$, take

$$\frac{1}{\sqrt{2\pi}}, \quad \frac{1}{\sqrt{\pi}} \cos \mu, \quad \frac{1}{\sqrt{\pi}} \sin \mu, \quad \frac{1}{\sqrt{\pi}} \cos 2\mu, \quad \frac{1}{\sqrt{\pi}} \sin 2\mu, \dots$$

The system is plainly normalized and orthogonal. Its completeness follows, for example, from Weierstrass's theorem that every continuous function of period 2π can be approximated uniformly by trigonometric polynomials, together with the fact that for every integrable $f(\mu)$ whose square is integrable, $\int_{-\pi}^{\pi} [f(\mu) - \varphi(\mu)]^2 d\mu$ may be made arbitrarily small by a suitable continuous function φ of period 2π . Applied to this special case, the formula in the text is Parseval's theorem, also called the fundamental theorem of Fourier constants. Cf. A. Hurwitz,

also normalized and orthogonal, the best choice of the c_k , for each n , is

$$c_k = f_k = \int_a^b f(\mu) \varphi_k(\mu) d\mu,$$

as follows immediately from

$$\int_a^b \left[f(\mu) - \sum_{k=1}^n c_k \varphi_k(\mu) \right]^2 d\mu = \int_a^b \left[f(\mu) - \sum_{k=1}^n f_k \varphi_k(\mu) \right]^2 d\mu + \sum_{k=1}^n (f_k - c_k)^2.$$

It follows that, as $n \rightarrow \infty$,

$$\int_a^b [f(\mu)]^2 d\mu - \sum_{k=1}^n f_k^2 = \int_a^b \left[f(\mu) - \sum_{k=1}^n f_k \varphi_k(\mu) \right]^2 d\mu \rightarrow 0;$$

that is,

$$\int_a^b [f(\mu)]^2 d\mu = \sum_{k=1}^{\infty} f_k^2.$$

Finally, applying this formula to $\frac{1}{2}[f(\mu) + g(\mu)]$ and $\frac{1}{2}[f(\mu) - g(\mu)]$, and subtracting, gives

$$\int_a^b f(\mu)g(\mu) d\mu = \sum_{k=1}^{\infty} \left(\int_a^b f(\mu) \varphi_k(\mu) d\mu \right) \left(\int_a^b g(\mu) \varphi_k(\mu) d\mu \right), \quad (24)$$

where f and g , as well as their squares, are assumed integrable.

All these considerations hold when *integral* is understood in Lebesgue's sense, and therefore *a fortiori* for the classical notion of integral. To fix ideas, suppose that the functions in question are continuous or consist of finitely many continuous pieces. Put

$$a_{ik} = \int_a^b u(\mu) \varphi_i(\mu) \varphi_k(\mu) d\mu, \quad A(x, x) = \sum_{i,k=1}^{\infty} a_{ik} x_i x_k.$$

The sections $[A(x, x)]_n$ and $[E(x, x)]_n$ are plainly represented by

$$\int_a^b u(\mu) \left[\sum_{k=1}^n x_k \varphi_k(\mu) \right]^2 d\mu, \quad \int_a^b \left[\sum_{k=1}^n x_k \varphi_k(\mu) \right]^2 d\mu.$$

"Über die Fourierschen Konstanten integrierbarer Funktionen," *Mathematische Annalen*, vol. LVII (1903), pp. 425–446, and vol. LIX (1904), p. 553; P. Fatou, "Séries trigonométriques et séries de Taylor," *Acta Mathematica*, vol. XXX (1906), pp. 335–400. Every system used below can easily be reduced to the case just considered.

Consequently $A(x, x)$ is bounded and, when $E(x, x) = 1$, the set of its values lies between the lower and upper bounds of $u(\mu)$. Let $A^*(x, x)$ be the form defined analogously by a function $u^*(\mu)$. Putting $f(\mu) = u(\mu)\varphi_i(\mu)$ and $g(\mu) = u^*(\mu)\varphi_k(\mu)$ in (24), we find that the coefficients of AA^* are

$$\int_a^b u(\mu)u^*(\mu)\varphi_i(\mu)\varphi_k(\mu) d\mu.$$

In particular, the coefficients of $A^2, A^3, \dots$ are obtained by replacing $u(\mu)$ with $u^2(\mu), u^3(\mu), \dots$ in the expression for a_{ik} .

It follows that the coefficients of $f(A)$ are

$$\int_a^b f[u(\mu)]\varphi_i(\mu)\varphi_k(\mu) d\mu.$$

This expression immediately opens the way to the study of the spectrum and the spectral forms. Let $\mathfrak{E}_\xi, \mathfrak{E}_\xi^\pm, \mathfrak{E}'_\xi$ denote the sets of values μ for which, respectively, $u(\mu) < \xi$, $u(\mu) \leq \xi$, and $u(\mu) = \xi$. The coefficients of $A_\xi, A_\xi^\pm, P_\xi$ are given by

$$\int \varphi_i(\mu)\varphi_k(\mu) d\mu,$$

where the integral extends over $\mathfrak{E}_\xi, \mathfrak{E}_\xi^\pm$, and $\mathfrak{E}'_\xi$, respectively. If, for example, $u(\mu)$ is continuous and has m and M as its extreme values, the spectrum is the interval $[m, M]$. If it takes neither the value ξ nor neighboring values, then ξ and its neighborhood do not belong to the spectrum. Finally, if it takes the value ξ throughout an interval, then ξ belongs to the point spectrum.

Form (23) belongs to this class on putting

$$a = 0, \quad b = \pi, \quad \varphi_k(\mu) = \sqrt{\frac{2}{\pi}} \sin k\mu, \quad u(\mu) = \cos \mu.$$

103. Consider another special case, intimately connected with the theory of trigonometric series. Here it is convenient to let the indices range from $-\infty$ to $+\infty$. This merely renumbers the variables x_k and therefore has no effect on the essential results of the theory.

Put

$$a = -\pi, \quad b = \pi, \quad \varphi_k(\mu) = \frac{1}{\sqrt{2\pi}}(\sin k\mu + \cos k\mu) = \frac{1}{\sqrt{\pi}} \cos \left(k\mu - \frac{\pi}{4}\right).$$

As k runs through all integers from $-\infty$ to $+\infty$, the $\varphi_k(\mu)$ form a normalized, complete orthogonal system. Consider the form

$$A(x, x) = \sum_{i, k=-\infty}^{+\infty} a_{ik} x_i x_k,$$

where

$$\begin{aligned} a_{ik} &= \int_{-\pi}^{\pi} u(\mu) \varphi_i(\mu) \varphi_k(\mu) d\mu \\ &= \frac{1}{2\pi} \int_{-\pi}^{\pi} u(\mu) \cos(i-k)\mu d\mu + \frac{1}{2\pi} \int_{-\pi}^{\pi} u(\mu) \sin(i+k)\mu d\mu. \end{aligned}$$

Denote the two terms on the right by α_{i-k} and β_{i+k} . Then $A(x, x)$ is the sum of the two forms

$$A^{(1)}(x, x) = \sum_{i, k=-\infty}^{+\infty} \alpha_{i-k} x_i x_k, \quad A^{(2)}(x, x) = \sum_{i, k=-\infty}^{+\infty} \beta_{i+k} x_i x_k.$$

The form $A^{(1)}$ corresponds to the even function

$$u^{(1)}(\mu) = \frac{u(\mu) + u(-\mu)}{2},$$

and $A^{(2)}$ to the odd function

$$u^{(2)}(\mu) = \frac{u(\mu) - u(-\mu)}{2}.$$

These forms belong to two very special types. The first, corresponding to even functions, was first considered by Toeplitz; we shall discuss it in the [next chapter](#).

The second corresponds to odd functions. For example, put

$$u(\mu) = \begin{cases} -\pi - \mu, & -\pi < \mu < 0, \\ \pi - \mu, & 0 < \mu < \pi. \end{cases}$$

The preceding integrals give

$$a_{ik} = \frac{1}{i+k} \quad (i+k \neq 0), \quad a_{ik} = 0 \quad (i+k = 0).$$

The lower and upper bounds of the piecewise-defined function $u(\mu)$ on $(-\pi, \pi)$ are $-\pi$ and π ^r; hence these are also the lower and upper bounds of $A(x, x)$, and

^r*Translator's note:* The French text mistakenly writes $u(\mu) = \mu$ here; the statement concerns the piecewise function just defined.

therefore, by no. 85, of the corresponding bilinear form $A(x, y)$. These forms include, in particular, the two forms considered by Hilbert:

$$\sum_{i,k=1}^{\infty} \frac{x_i x_k}{i+k}, \quad \sum_{\substack{i,k=1 \\ i \neq k}}^{\infty} \frac{x_i y_k}{i-k}.$$

The first is obtained from $A(x, x)$ by putting $x_0 = x_{-1} = x_{-2} = \cdots = 0$; the second is obtained from $A(x, y)$ by putting $x_0 = x_{-1} = x_{-2} = \cdots = 0$, $y_0 = y_1 = y_2 = \cdots = 0$, and then reversing the signs of the indices of the y 's. Thus, under $E(x, x) \leq 1$, $E(y, y) \leq 1$, both forms remain between $-\pi$ and π .

The special interest of these forms lies in the fact that they stand, so to speak, on the boundary of the class of bounded forms. Indeed, very similar expressions fail to represent bounded forms. Consider, for example, the following expression.^s

$$\sum_{i,k=1}^{\infty} \frac{x_i x_k}{(i+k)^{\alpha}}, \quad \alpha < 1.$$

Put $x_1 = x_2 = \cdots = x_n = 1/\sqrt{n}$ and $x_{n+1} = x_{n+2} = \cdots = 0$, consistently with $E(x, x) = 1$. If $0 \leq \alpha < 1$, all terms for which $i+k \leq n+1$ are at least $1/[n(n+1)^{\alpha}]$, and there are $1+2+\cdots+n = n(n+1)/2$ of them; thus the value of the expression is at least $\frac{1}{2}(n+1)^{1-\alpha}$, and grows without bound with n . If $\alpha < 0$, all n^2 nonzero terms are at least $2^{-\alpha}/n$, so their sum is at least $2^{-\alpha}n$ and is again unbounded. Likewise, making the same choice in

$$\sum_{\substack{i,k=1 \\ i \neq k}}^{\infty} \frac{x_i x_k}{|i-k|}$$

gives

$$2 \left(1 + \frac{1}{2} + \cdots + \frac{1}{n-1} \right) - \frac{2(n-1)}{n},$$

which also grows without bound.¹⁶

^sTranslator's note: The French proof treats all $\alpha < 1$ with the first estimate below, which directly applies only when $0 \leq \alpha < 1$. The omitted case $\alpha < 0$ is supplied separately.

¹⁶The latter fact may be expressed by saying that the bounded bilinear form $\sum_{i,k=1, i \neq k}^{\infty} x_i y_k / (i-k)$ is not absolutely bounded. It was noted by Hellinger and Toeplitz in their memoir cited in no. 57, p. 308. For analogous forms, cf. O. Toeplitz, "Zur Theorie der quadratischen Formen von unendlich vielen Veränderlichen," *Nachrichten der Königlichen Gesellschaft der Wissenschaften zu Göttingen* (1910), pp. 489–506; and I. Schur, "Bemerkungen zur Theorie der beschränkten Bilinearformen mit unendlich vielen Veränderlichen," *Journal für die reine und angewandte Mathematik*, vol. CXL (1911), pp. 1–28.

Chapter VI.

Applications

Linear Differential Equations

104. While studying the method of infinite determinants in [Chapter II](#), we stated that this method was invented and first applied by Hill to the linear differential equation

$$\frac{d^2 w}{dt^2} + (\theta_0 + 2\theta_1 \cos t + 2\theta_2 \cos 2t + \cdots)w = 0. \quad (1)$$

The argument of the learned astronomer, too concise for the pure geometer, was perfected and fully justified by Poincaré. We have presented Poincaré's argument, as well as later investigations into the convergence of infinite determinants and their application to systems of linear equations in infinitely many unknowns. We did not, however, return to equation (1). We do so now, but instead of considering only the special equation (1),¹ we shall follow von Koch in placing ourselves in a more general setting.

Consider the homogeneous linear differential equation of order n

$$\frac{d^n u}{dz^n} + P_1(z) \frac{d^{n-1} u}{dz^{n-1}} + P_2(z) \frac{d^{n-2} u}{dz^{n-2}} + \cdots + P_n(z)u = 0, \quad (2)$$

where the coefficients $P_1(z), \dots, P_n(z)$ have Laurent expansions

$$P_m(z) = \sum_{k=-\infty}^{+\infty} a_{mk} z^k, \quad (3)$$

convergent in the circular annulus $r < |z| < R$. From the investigations of Fuchs it is known that there exists at least one integral of the form

$$u(z) = z^\rho \sum_{k=-\infty}^{+\infty} \alpha_k z^k,$$

¹Equation (1) was studied in detail by Poincaré, loc. cit.; see [nos. 17 and 19](#).

where the Laurent series converges in the annulus. Our task is to determine the constant ρ and the coefficients α_k so that $u(z)$ is an integral of (2).

Equation (1) plainly belongs to this class if the function $\theta(t) = \theta_0 + 2\theta_1 \cos t + \dots$ is holomorphic for real values of t , and if in addition we make the change of variable $z = e^{it}$.

105. First observe that, without loss of generality, we may suppose $P_1(z) = 0$ and $r < 1 < R$. Indeed, these assumptions amount to replacing u and z , respectively, by

$$u' = u \exp \left(-\frac{1}{n} \int P_1(z) dz \right), \quad z' = \frac{z}{\sqrt{Rr}};$$

the modified equation plainly satisfies the assumptions made.

Substitute the expansions of $P_m(z)$ and $u(z)$ into (2). Comparing coefficients gives the equations

$$\sum_{k=-\infty}^{+\infty} \varphi_{i-k}(\rho + k) \alpha_k = 0, \quad i = -\infty, \dots, +\infty, \quad (4)$$

where

$$\begin{aligned} \varphi_0(\rho) &= \rho(\rho - 1) \cdots (\rho - n + 1) \\ &\quad + \rho(\rho - 1) \cdots (\rho - n + 3) a_{2,-2} + \cdots + \rho a_{n-1,-n+1} + a_{n,-n}, \end{aligned}$$

and, for $j \neq 0$,

$$\varphi_j(\rho) = \rho(\rho - 1) \cdots (\rho - n + 3) a_{2,j-2} + \cdots + \rho a_{n-1,j-n+1} + a_{n,j-n}.$$

To put (4) into the form

$$\sum_{k=-\infty}^{+\infty} \psi_{ik}(\rho) \alpha_k = 0, \quad i = -\infty, \dots, +\infty, \quad (5)$$

with $\psi_{ii} = 1$ for every i , put

$$\psi_{ik}(\rho) = \frac{\varphi_{i-k}(\rho + k)}{\varphi_0(\rho + i)}.$$

Let $\rho_1, \dots, \rho_n$ be the roots of $\varphi_0(\rho) = 0$. The poles of the rational functions $\psi_{ik}(\rho)$ then belong to the set of values $\rho_1 - i, \dots, \rho_n - i$, $i = -\infty, \dots, +\infty$, which are the roots of one or another of the equations $\varphi_0(\rho + i) = 0$.

In the ρ -plane consider a finite or infinite domain D , lying between two lines parallel to the imaginary axis, such that none of these roots lies in its interior or on its boundary. We shall show that

$$\sum_{\substack{i,k=-\infty \\ i \neq k}}^{+\infty} |\psi_{ik}(\rho)| \quad (6)$$

converges uniformly in D .

For this purpose, write the polynomials $\varphi_j(\rho + i - j)$, $j \neq 0$, in the form

$$H_2(j)(\rho + i)^{n-2} + H_3(j)(\rho + i)^{n-3} + \cdots + H_n(j).$$

Each $H_r(j)$ is a sum of finitely many terms of the form $j^q a_{mj}$, $q = 0, 1, 2, \dots$. The Laurent series (3) converge in an annulus containing $|z| = 1$; hence the series

$$\sum_{j=-\infty}^{+\infty} |j^q a_{mj}| \quad (q = 0, 1, 2, \dots)$$

converge, and therefore so do

$$S_r = \sum_{j=-\infty}^{+\infty} |H_r(j)|, \quad r = 2, 3, \dots, n.$$

By the hypothesis on D , there is a constant C_1 such that

$$\frac{1}{|\varphi_0(\rho + i)|} < \frac{C_1}{(1 + |i|)^n},$$

and a constant C_2 such that $|\rho + i| < C_2(1 + |i|)$. Consequently,

$$\sum_{\substack{i,k=-\infty \\ i \neq k}}^{+\infty} |\psi_{ik}(\rho)| \leq (S_2 + S_3 + \cdots + S_n) C_3 \sum_{i=-\infty}^{+\infty} \frac{1}{(1 + |i|)^2},$$

which proves the uniform convergence of (6).

It follows that the infinite determinant $\Omega(\rho)$ corresponding to (5) is of normal type. It and its minors converge for every ρ , except perhaps at roots of the equations $\varphi_0(\rho + i) = 0$, and the convergence is uniform in every domain D of the kind just described. Thus $\Omega(\rho)$ is holomorphic except at those roots, where it has the

character of a rational function. The last assertion follows because any one value ρ can satisfy only finitely many of the equations $\varphi_0(\rho + i) = 0$. More precisely, ρ is a pole of order m of $\Omega(\rho)$ if exactly m roots of $\varphi_0(\rho) = 0$, counted with multiplicity, differ from ρ by an integer or by zero.

The function $\Omega(\rho)$ has period one, since

$$\psi_{ik}(\rho + 1) = \psi_{i+1, k+1}(\rho),$$

and replacing ρ by $\rho + 1$ therefore does not change the determinant. Moreover, as $\rho \rightarrow \infty$ while its real part remains bounded, the functions $\psi_{ik}(\rho)$, $i \neq k$, tend to zero; hence $\Omega(\rho) \rightarrow 1$. Consequently, $\Omega(\rho)$ is a rational function $R(\omega)$ of

$$\omega = e^{2\pi i \rho},$$

and $R(0) = R(\infty) = 1$. The poles of R necessarily have the form $\omega_k = e^{2\pi i \rho_k}$; more precisely, ω is a pole of order m if it occurs m times among $\omega_1, \dots, \omega_n$. Thus

$$R(\omega) = \frac{P(\omega)}{(\omega - \omega_1)(\omega - \omega_2) \cdots (\omega - \omega_n)},$$

where P is a polynomial. Let $\omega^{(1)}, \omega^{(2)}, \dots$ be the roots of P , and write

$$P(\omega) = C(\omega - \omega^{(1)})(\omega - \omega^{(2)}) \cdots.$$

The relation $R(\infty) = 1$ shows that P too has degree n and that $C = 1$; the relation $R(0) = 1$ gives

$$\omega^{(1)} \omega^{(2)} \cdots \omega^{(n)} = \omega_1 \omega_2 \cdots \omega_n.$$

On putting

$$\rho^{(k)} = \frac{1}{2\pi i} \log \omega^{(k)},$$

we may therefore choose the branches of the logarithms so that

$$\rho^{(1)} + \cdots + \rho^{(n)} = \rho_1 + \cdots + \rho_n.$$

It follows that

$$\Omega(\rho) = \prod_{k=1}^n \frac{\sin \pi(\rho - \rho^{(k)})}{\sin \pi(\rho - \rho_k)}.$$

106. Consider now the system obtained from (4) by multiplying each equation by the corresponding function

$$h_0(\rho) = 1,$$

$$h_i(\rho) = \frac{1}{i^n} \exp\left(-\frac{\rho - \rho_1}{i}\right) \exp\left(-\frac{\rho - \rho_2}{i}\right) \cdots \exp\left(-\frac{\rho - \rho_n}{i}\right), \quad i \neq 0.$$

where the ρ_k are the roots of $\varphi_0(\rho) = 0$. The coefficients of this new system are entire functions of ρ , and the same is true of its determinant $\Delta(\rho)$. This determinant is of normal type and, together with its minors, converges for every ρ . Moreover,

$$\Delta(\rho) = \Pi(\rho)\Omega(\rho), \quad \Pi(\rho) = \prod_{k=1}^n \frac{\sin \pi(\rho - \rho_k)}{\pi}.$$

Indeed, the entries of $\Delta(\rho)$ are

$$\chi_{ik}(\rho) = h_i(\rho)\varphi_0(\rho + i)\psi_{ik}(\rho),$$

and the infinite product formed from the diagonal entries

$$\chi_{ii}(\rho) = \prod_{k=1}^n \left(1 + \frac{\rho - \rho_k}{i}\right) \exp\left(-\frac{\rho - \rho_k}{i}\right)$$

converges absolutely to $\Pi(\rho)$, uniformly in every bounded domain.

Thus

$$\Delta(\rho) = \prod_{k=1}^n \frac{\sin \pi(\rho - \rho^{(k)})}{\pi}.$$

In $\Delta(\rho)$, replace the entries χ_{ik} of the row numbered i by the corresponding quantities z^k , and denote the modified determinant by $\Delta_i(\rho, z)$. When $|z| = 1$, these quantities are bounded as a whole, so the modified determinant converges absolutely. More is true: it converges absolutely for every z_0 in the annulus $r < |z_0| < R$.

To see this, first replace $\chi_{ik}(\rho)$ in $\Delta(\rho)$ by $\chi_{ik}(\rho)z_0^{i-k}$, or equivalently replace $\varphi_j(\rho)$ by $\varphi_j(\rho)z_0^j$. This determinant is again of normal type. Indeed, on introducing the new variable $z' = z/z_0$ in the differential equation, $\Delta(\rho)$ is replaced by precisely this modified determinant, and all the preceding arguments apply. Now replace all entries of its row numbered i by z_0^i ; the resulting determinant converges absolutely. Absolute convergence is preserved when each entry is multiplied by the corresponding quantity z_0^{k-i} . This produces $\Delta_i(\rho, z_0)$, proving the assertion.

107. When $\Delta(\rho) \neq 0$, system (4) has, besides the evident zero solution, no solution (α_k) for which the α_k are bounded as a whole. Consequently, (2) has no solution of the form $z^\rho \sum_k \alpha_k z^k$.

Let ρ' now be a root of $\Delta(\rho)$. Suppose there is an index i for which at least one first minor $M_{ik}(\rho')$ of $\Delta(\rho')$ does not vanish. Then, apart from an arbitrary common factor, equations (4) have the unique solution $\alpha_k = M_{ik}(\rho')$. From the result just proved for $\Delta_i(\rho, z)$, the series

$$\sum_{k=-\infty}^{+\infty} M_{ik}(\rho') z^k = \Delta_i(\rho', z)$$

converges whenever $r < |z| < R$. Therefore

$$z^{\rho'} \Delta_i(\rho', z)$$

is the required solution $u(z)$ for $\rho = \rho'$, and it is unique up to a constant factor.

We have supposed that for $\rho = \rho'$ there is a minor $M_{ik}(\rho') \neq 0$. This is always so when ρ' is a simple root of $\Delta(\rho)$. Indeed, the formula

$$\frac{d\Delta}{d\rho} = \sum_{i,k=-\infty}^{+\infty} \frac{d\chi_{ik}}{d\rho} M_{ik}$$

shows at once that if $M_{ik}(\rho') = 0$ for every i, k , then $d\Delta/d\rho = 0$; hence ρ' is not a simple root.

If the quantities $\rho^{(1)}, \dots, \rho^{(n)}$ are all distinct and no two differ by an integer, all roots of $\Delta(\rho)$ are simple. Otherwise there are multiple roots, and at such a root all first minors may vanish. Let ρ' be a root of order m . Expanding $[d^m \Delta / d\rho^m]_{\rho=\rho'}$ in terms of minors of order m , one sees immediately that at least one such minor is nonzero. It follows that system (4), for $\rho = \rho'$, has a certain number $g \leq m$ of independent solutions, given by minors of $\Delta(\rho')$; each of these solutions gives rise to a solution of the differential equation.

Von Koch carried the study of $\Delta(\rho)$ still further by applying to infinite determinants the principles of the theory of elementary divisors. In this way he was able to calculate and study anew the fundamental systems of n independent integrals of the differential equation. I shall not enter into the details; the interested reader will profit greatly from consulting the original memoir.²

²H. von Koch, "Sur les intégrales régulières des équations différentielles linéaires," *Acta Mathematica*, vol. XVIII (1894), pp. 337–419.

Integral Equations

108. The reader is doubtless aware of the special importance recently attached to the theory of integral equations.

The fundamental principles of this young theory have already been set forth in excellent treatises, and I may confine myself to the questions most closely connected with our subject.

In his fifth memoir on linear integral equations, published in 1906, Hilbert reduced the solution of these functional equations to the solution of infinite systems of linear equations in infinitely many unknowns. The fourth memoir, published shortly before and already discussed by us, had as its principal purpose to prepare this application. Since then, most of the results forming the subject of the present volume have been translated into corresponding results on integral equations.^{3†}

The relations between the two theories are not limited to a formal analogy; their objects can be put into an actual correspondence. The germ of this correspondence is the application of the method of undetermined coefficients to series in orthogonal functions. Consider, for example, the integral equation of the second kind

$$\varphi(s) - \int_a^b H(s, t)\varphi(t) dt = f(s), \quad (7)$$

and suppose it can be satisfied by a function of the form

$$\varphi(s) = \sum_{k=1}^{\infty} \varphi_k \alpha_k(s),$$

where the functions $\alpha_k(s)$ form a normalized orthogonal system on (a, b) . Substitute this expansion in the equation, multiply successively by the $\alpha_i(s)$, and integrate with respect to s . The integral equation becomes the system

$$\varphi_i - \sum_{k=1}^{\infty} h_{ik} \varphi_k = f_i, \quad i = 1, 2, \dots, \quad (8)$$

³Besides Hilbert's fifth memoir, cf. H. Weyl, "Singuläre Integralgleichungen," *Mathematische Annalen*, vol. LXVI (1908), pp. 273–324; M. Plancherel, "Note sur les équations intégrales singulières," *Rivista di Fisica, Matematica e Scienze Naturali* (Pavia, 1909), pp. 37–53; A. J. Pell, "Biorthogonal Systems of Functions," *Transactions of the American Mathematical Society*, vol. XII (1911), pp. 135–164.

[†]Translator's note: The French original prints "vol. XIX"; the article appeared in vol. XII.

in the unknowns φ_k , where

$$h_{ik} = \int_a^b ds \int_a^b H(s, t) \alpha_i(s) \alpha_k(t) dt, \quad f_i = \int_a^b f(s) \alpha_i(s) ds.$$

To make this argument rigorous, one must first state precisely the hypotheses on the functions entering the calculation and then prove that, under those hypotheses, the passage from (7) to (8) is permissible. Suppose further that the hypotheses have been chosen so that (8) can be treated by one of the methods developed above and has a solution (φ_k). A new difficulty then arises. It is not enough to pass from (7) to (8); one must also be able to return. Once the quantities φ_k have been determined, one must construct the function $\varphi(s)$. In general the series $\sum_k \varphi_k \alpha_k(s)$ will not converge; it will be only, so to speak, a formal expansion of the desired function.

All these questions belong to the theory of integration, and different means of treating them are known in different cases. In many special cases the classical theory of integration, going back to Cauchy, already supplies what is needed. But if one always confined oneself to that classical theory, unexpected complications would arise even in apparently simple cases. We prefer from the outset to base the discussion on Lebesgue's notion of the integral.

109. Consider real functions $\alpha_1(s), \alpha_2(s), \dots$, defined on (a, b) , normalized and pairwise orthogonal. Let $f(s)$ be a real function on the same interval, integrable and with integrable square. The *coordinates* of $f(s)$ relative to the system $[\alpha_k(s)]$ are the quantities

$$f_k = \int_a^b f(s) \alpha_k(s) ds.$$

Bessel's familiar identity

$$\int_a^b \left[f(s) - \sum_{k=1}^n f_k \alpha_k(s) \right]^2 ds = \int_a^b [f(s)]^2 ds - \sum_{k=1}^n f_k^2$$

gives the inequality

$$\sum_{k=1}^n f_k^2 \leq \int_a^b [f(s)]^2 ds.$$

Thus the series $\sum_k f_k^2$ converges. One may ask whether the converse is also true: given a sequence of numbers f_k such that $\sum_k f_k^2$ converges, does there exist a function $f(s)$ having these numbers as its coordinates?

For the answer to be affirmative, it is indispensable to understand the word *integral* in Lebesgue's sense. With this understanding, I proved that there do indeed exist summable functions $f(s)$ (Lebesgue-integrable functions) with summable squares and prescribed coordinates f_k .⁴ Such a function is obtained by considering the uniformly convergent series^u

$$F(s) = \sum_{k=1}^{\infty} f_k \int_a^s \alpha_k(t) dt.$$

The function $F(s)$ has a derivative except perhaps at values of s forming a set of measure zero. Define $f(s)$ to equal this derivative wherever it exists and give it arbitrary values at all remaining points. Then $f(s)$ is summable, has summable square, and has the f_k as coordinates. Moreover,

$$\int_a^b [f(s)]^2 ds = \sum_{k=1}^{\infty} f_k^2. \quad (9)$$

Recall also that if the system $[\alpha_k(s)]$ is complete, formula (9) holds for every real summable function $f(s)$ with summable square and coordinates f_k ; see [no. 102](#). In particular, if $f_1(s)$ and $f_2(s)$ have the same coordinates, then $f_1(s) - f_2(s)$ has every coordinate zero, and the integral of $[f_1(s) - f_2(s)]^2$ vanishes. Thus $f_1(s) = f_2(s)$, except perhaps on a set of measure zero. In view of the role of such sets in Lebesgue's theory, one may simply say that a function $f(s)$ is uniquely determined by its coordinates.

Finally recall the formula

$$\int_a^b f(s)g(s) ds = \sum_{k=1}^{\infty} f_k g_k, \quad (10)$$

obtained by applying (9) to $\frac{1}{2}[f(s) + g(s)]$ and $\frac{1}{2}[f(s) - g(s)]$, and subtracting the second expansion from the first.

⁴F. Riesz, "Sur les systèmes orthogonaux de fonctions," *Comptes rendus*, March 18, 1907. The same fact was discovered independently by E. Fischer, "Sur la convergence en moyenne," *Comptes rendus*, May 13, 1907. For a detailed proof and further bibliographical references, see my memoir "Untersuchungen über Systeme integrierbarer Funktionen," *Mathematische Annalen*, vol. LXIX (1910), pp. 449–497, or the recent exposition by W. H. Young and G. C. Young, "On the Theorem of Riesz–Fischer," *Quarterly Journal of Mathematics*, vol. XLIV (1912), pp. 49–88.

^uTranslator's note: The printed formula uses s both as the upper limit and as the variable of integration; t has been substituted as the dummy variable.

These results extend immediately when $f(s), g(s)$ and the coordinates f_k, g_k are no longer assumed real; one merely replaces squares by squares of absolute values. It is not even essential that the functions $\alpha_k(s)$ be real; the definitions and statements need only slight modification.

All the results likewise extend to functions of several variables. In particular, if $[\alpha_k(s)]$ is a normalized, complete orthogonal system of real functions on (a, b) , then $[\alpha_i(s)\alpha_k(t)]$ is such a system on the square $a \leq s \leq b, a \leq t \leq b$, and

$$\begin{aligned} & \int_a^b \int_a^b f(s, t) g(s, t) ds dt \\ &= \sum_{i,k=1}^{\infty} \left(\int_a^b \int_a^b f(s, t) \alpha_i(s) \alpha_k(t) ds dt \right) \left(\int_a^b \int_a^b g(s, t) \alpha_i(s) \alpha_k(t) ds dt \right), \end{aligned} \quad (11)$$

where $f(s, t)$ and $g(s, t)$, as well as their squares, are assumed summable.

110. Consider the integral equation (7). To begin with a simple case, suppose that $H(s, t)$ and $f(s)$ are continuous. Using a normalized, complete orthogonal system of real functions $\alpha_k(s)$, the passage from (7) to (8) is made by replacing $g(s)$ in (10) by $\alpha_i(s)$, and by replacing $f(s, t)$ and $g(s, t)$ in (11) by $H(s, t)$ and $\alpha_i(s)\alpha_k(t)$, respectively. Since

$$\sum_{i,k=1}^{\infty} |h_{ik}|^2 = \int_a^b \int_a^b |H(s, t)|^2 ds dt \quad (12)$$

converges, the substitution defined by (h_{ik}) is completely continuous. All the results concerning this special class of linear substitutions may therefore be applied both to (8) and to its associated homogeneous system.

At the same time one may consider the transposed equation

$$\psi(t) - \int_a^b H(s, t) \psi(s) ds = g(t), \quad (13)$$

which, by means of the orthogonal system $[\alpha_k(s)]$, becomes

$$\psi_k - \sum_{i=1}^{\infty} h_{ik} \psi_i = g_k, \quad k = 1, 2, \dots, \quad (14)$$

in the unknowns ψ_k . Every solution (φ_k) of (8) for which $\sum_k |\varphi_k|^2$ converges corresponds to a summable function $\varphi(s)$ with summable $|\varphi(s)|^2$; the same is true

of every admissible solution (ψ_k) of (14).^v The function

$$\varphi(s) - \int_a^b H(s, t)\varphi(t) dt,$$

whose coordinates are $\varphi_i - \sum_{k=1}^{\infty} h_{ik}\varphi_k = f_i$, equals $f(s)$, except perhaps on a set of measure zero. But the coordinates determine $\varphi(s)$ only up to the addition of a function that vanishes almost everywhere.^w This indeterminacy can be used to obtain an exact solution of (7): the equation itself makes the necessary correction. Indeed,

$$\varphi^*(s) = f(s) + \int_a^b H(s, t)\varphi(t) dt$$

is continuous, has the same coordinates as $\varphi(s)$, and hence satisfies (7) exactly.

The same argument applies to (13).

These brief indications should suffice to show how every result about completely continuous substitutions and their corresponding systems of equations can be translated into a result about integral equations. It is also easy to see that continuity of $H(s, t)$ is not essential. In fact, most of the preceding argument remains unchanged if one assumes only that

$$H(s, t), \quad |H(s, t)|^2, \quad f(s), \quad |f(s)|^2, \quad g(s), \quad |g(s)|^2$$

are summable. Even if, for example, one wants to ensure that the solution $\varphi^*(s)$ is continuous, it is enough, instead of assuming the kernel $H(s, t)$ continuous, to choose it so that the first of the integrals^x

$$\int_a^t H(s, \tau) d\tau, \quad \int_a^b |H(s, t)|^2 dt$$

represents a continuous function of s for every t , and the second represents a bounded function. The kernels $|s - t|^{-\alpha}$, with $\alpha < \frac{1}{2}$, are examples.

Finally, convergence of (12) also permits the method of infinite determinants to be applied to systems (8) and (14). By an easy calculation, one can even recover in

^vTranslator's note: The French original refers here to equation (15); equation (14) is meant.

^wTranslator's note: The French original says "a function whose integral is zero." Completeness of the orthogonal system instead implies that the difference has squared modulus with integral zero, hence vanishes almost everywhere.

^xTranslator's note: In the first printed integral, t appears both as the upper limit and as the variable of integration; τ has been substituted as the dummy variable.

this way all Fredholm's formulas.⁵

111. To approach equations whose kernels have higher singularities, we introduce the notion of a linear functional transformation. To every function $f(s)$ of the kind considered—summable together with $|f|^2$ —associate a function $f'(s)$ of the same kind, in such a way that

$$f'_1 + f'_2 = (f_1 + f_2)', \quad c f' = (c f)',$$

and suppose in addition that there is a constant M^2 such that, for every function $f(s)$,

$$\int_a^b |f'(s)|^2 ds \leq M^2 \int_a^b |f(s)|^2 ds. \quad (15)$$

Definition. Every correspondence of this kind is called a *linear transformation*.

It is evident that, by associating the coordinates of $f'(s)$ with those of $f(s)$, one defines a linear substitution of Hilbert space. Conversely, if to each function $f(s)$ of the kind considered we associate the function $f'(s)$ whose coordinates are obtained by applying a linear substitution A to those of $f(s)$, then a linear functional transformation has been defined.

I do not propose to pursue every detail of this relation between transformations and linear substitutions. Plainly the whole theory of linear substitutions developed in [Chapter IV](#) can be translated into a theory of linear functional transformations.

In particular, under the conditions previously imposed on $H(s, t)$, the integral

$$f'(s) = \int_a^b H(s, t) f(t) dt \quad (16)$$

represents a linear transformation. The conditions imposed on $H(s, t)$ are not essential; in any event, it is enough that (16) exist and that (15) hold. I hasten to observe, however, that (16) does not exhaust the possibilities. The identity transformation $f'(s) = f(s)$, and the transformation $f'(s) = g(s)f(s)$, where $g(s)$ is summable and bounded, cannot be put in this form.⁶ This observation gives rise to the question discussed in the next paragraph.

⁵Cf. E. Marty, "Transformation d'un déterminant infini en un déterminant de Fredholm," *Bulletin des Sciences mathématiques*, vol. XXXIII (1909), pp. 296–300; J. Møllerup, "Sur l'identité du déterminant de Fredholm et d'un déterminant infini de v. Koch," *ibid.*, vol. XXXVI (1912), pp. 130–136. Marty assumes that $\sum_{i,k} |h_{ik}|$ converges; Møllerup adopts the assumption used in the text.

⁶A detailed study of the analytic representation of linear functional transformations was given by M. Plancherel in "Contribution à l'étude de la représentation d'une fonction arbitraire par des intégrales définies," *Rendiconti del Circolo Matematico di Palermo*, vol. XXX (1910), pp. 289–335.

112. The study of a linear substitution A brings in other related substitutions: recall its transpose $\mathfrak{A}$, its iterates A^k , the inverses A^{-1} and $(E - A)^{-1}$, the substitutions $A^{(k)}$ studied in no. 82, and, when A is real and symmetric, all substitutions $f(A)$. Suppose now that a linear transformation of the form (16) is under consideration. By means of an orthogonal system $[\alpha_k(s)]$, it corresponds to a linear substitution A . This substitution gives rise to those just recalled, and each of them, through the same orthogonal system, corresponds to a linear functional transformation. For each such transformation one may ask whether it can be put in either of the forms

$$\int_a^b G(s, t) f(t) dt, \quad c f(s) + \int_a^b G(s, t) f(t) dt.$$

For the transformations corresponding to $\mathfrak{A}$ and the A^k , the question reduces at once to interchanging the order of certain successive integrations, and I shall not dwell on it. For A^{-1} , one is led to the delicate problem of integral equations of the first kind, which cannot be summarized in a few lines. For $(E - A)^{-1}$, the question involves one of the fundamental problems in the theory of integral equations of the second kind. Since Fredholm's investigations it has been known that, in the simplest cases, the solution of (7) can be put in the form

$$\varphi(s) = f(s) + \int_a^b G(s, t) f(t) dt,$$

where $G(s, t)$, called the *resolvent kernel*, is independent of the given function $f(s)$.

This fact may be attached to the relation

$$(E - A)^{-1} = E + (E - A)^{-1}A.$$

It shows that, to calculate $G(s, t)$, one need only apply to $H(s, t)$, regarded as a function of s , the linear transformation corresponding to $(E - A)^{-1}$. The legitimacy of this procedure is evident when, for example, the kernel is continuous; it also applies when the kernel has high singularities. Everything plainly reduces to proving that the order of certain passages to the limit may be interchanged.

The same reasoning applies to all substitutions $f(A)$ which can be put in the form $cE + f_1(A)A$. I cannot enter into details without going deeply into the theory of integration; readers familiar with that theory will readily supply the necessary arguments.

Finally, it should be observed that not only the results, but almost all the arguments concerning systems of equations in infinitely many unknowns have

their analogues in the theory of integral equations. This analogy may be used when the consideration of summable functions with summable squares is not suited to the data of the problem.

Trigonometric Series

113. Given a sequence extending indefinitely in both directions (α_k) , attach to it a matrix (a_{ik}) by putting $a_{ik} = \alpha_{k-i}$. This matrix belongs to a special type which we shall call the *Laurent type*, because of its relation to the series

$$\sum_{k=-\infty}^{+\infty} \alpha_k z^k.$$

The theory of Laurent substitutions and forms corresponding to these special matrices is due to Toeplitz.⁷

The problem which leads most immediately to Laurent matrices is the following. If one seeks the Laurent expansion of the quotient of two functions given by their Laurent expansions, the method of undetermined coefficients plainly leads to a system of linear equations in infinitely many unknowns; the coefficients of these equations form the Laurent matrix corresponding to the series in the denominator. We encountered a special problem of this kind in [no. 13](#), where we discussed a note of Appell.

We prefer to adopt at once a more general standpoint, connecting Laurent substitutions and forms with the theory of systems of orthogonal functions. Recall that we already alluded to this in [no. 103](#), where the coefficients of certain quadratic forms were Fourier coefficients.

114. Consider the functions

$$\varphi_k(s) = e^{2\pi i k s} = \cos 2\pi k s + i \sin 2\pi k s,$$

where k ranges indefinitely in both directions. Plainly,

$$\int_{-1/2}^{1/2} \varphi_k(s) \overline{\varphi_l(s)} ds = \int_{-1/2}^{1/2} e^{2\pi i(k-l)s} ds = \begin{cases} 1, & k = l, \\ 0, & k \neq l. \end{cases}$$

⁷O. Toeplitz, "Zur Transformation der Scharen bilinearer Formen von unendlich vielen Veränderlichen," *Nachrichten der Königl. Gesellschaft der Wissenschaften zu Göttingen* (1907), pp. 110–116; "Zur Theorie der quadratischen Formen von unendlich vielen Veränderlichen," *ibid.* (1910), pp. 489–506; "Zur Theorie der quadratischen und bilinearen Formen von unendlich vielen Veränderlichen," *Mathematische Annalen*, vol. LXX (1911), pp. 351–376.

The system is complete on $(-\frac{1}{2}, \frac{1}{2})$, as follows immediately from the analogous property of $(\cos 2\pi ks, \sin 2\pi ks)$, $k = 0, 1, 2, \dots$. Thus the φ_k form a normalized, complete orthogonal system on this interval.⁸ The coordinates of a function $f(s)$ relative to this system are

$$f_k = \int_{-1/2}^{1/2} f(s) \overline{\varphi_k(s)} ds.$$

All the results concerning orthogonal systems of real functions in nos. 102 and 109 apply, with evident modifications, to $\varphi_k(s)$. In particular, if f_k and g_k are the coordinates of functions $f(s)$ and $g(s)$, summable together with $|f(s)|^2$ and $|g(s)|^2$, then $\int f(s)g(s) ds = \sum_k f_{-k}g_k$. Moreover, the coordinate numbered i of $f(-s)\varphi_k(s)$ is plainly f_{k-i} , and hence

$$\int_{-1/2}^{1/2} f(-s)g(s) \overline{\varphi_i(s)} ds = \sum_{k=-\infty}^{+\infty} f_{k-i}g_k. \quad (17)$$

Suppose now that the matrix $(a_{ik} = \alpha_{k-i})$ defines a linear (distributive and bounded) substitution of Hilbert space,

$$x'_i = \sum_{k=-\infty}^{+\infty} \alpha_{k-i}x_k, \quad i = -\infty, \dots, +\infty. \quad (18)$$

The series $\sum_k |\alpha_k|^2$ then converges, and the α_k are the coordinates of a function $\alpha(s)$, summable together with $|\alpha(s)|^2$. Let $x(s)$ be the function of the same kind whose coordinates are the x_k . Consider

$$x'(s) = \alpha(-s)x(s).$$

By (17), the coordinates x'_k of this function are given by (18). Thus the orthogonal system $[\varphi_k(s)]$ associates with the substitution $A = (\alpha_{k-i})$ the functional transformation $x'(s) = \alpha(-s)x(s)$. Since $\sum_k |x_k|^2$ and $\sum_k |x'_k|^2$ represent the integrals of $|x(s)|^2$ and $|x'(s)|^2$, respectively,

$$\int_{-1/2}^{1/2} |\alpha(-s)x(s)|^2 ds \leq M_A^2 \int_{-1/2}^{1/2} |x(s)|^2 ds. \quad (19)$$

⁸Instead of $[\varphi_k(s)]$, we could have used the more familiar system (e^{iks}) on $(-\pi, \pi)$ or $(0, 2\pi)$; that choice would, however, have burdened the formulas with inessential numerical constants.

Let $\mathfrak{E}$ be the set of values s for which $|\alpha(-s)| > M_A$, and put $x(s) = 1$ on this set and zero elsewhere. Inequality (19) gives

$$\int_{\mathfrak{E}} |\alpha(-s)|^2 ds \leq M_A^2 \int_{\mathfrak{E}} ds.$$

Since $|\alpha(-s)| > M_A$ on $\mathfrak{E}$, the set $\mathfrak{E}$ must have measure zero. The function $\alpha(s)$ may be modified arbitrarily there without changing its coordinates; consequently, we may suppose that $|\alpha(s)| \leq M_A$ everywhere.

An analogous argument shows that if the Hermitian form

$$\sum_{i=-\infty}^{+\infty} \left| \sum_{k=-\infty}^{+\infty} \alpha_{k-i} x_k \right|^2 = \int_{-1/2}^{1/2} |\alpha(-s)x(s)|^2 ds \quad (20)$$

remains at least J^2 whenever $\sum_k |x_k|^2 = 1$, then the set on which $|\alpha(-s)| < J$ has measure zero. Thus we may also suppose that $|\alpha(s)| \geq J$ everywhere.

Conversely, given a bounded summable function $\alpha(s)$, its coordinates α_k define a linear substitution $A = (\alpha_{k-i})$. Indeed, if $|\alpha(s)| \leq M$, and if $x(s)$ and $|x(s)|^2$ are summable, then so are $x'(s) = \alpha(-s)x(s)$ and $|x'(s)|^2$, and

$$\int_{-1/2}^{1/2} |x'(s)|^2 ds \leq M^2 \int_{-1/2}^{1/2} |x(s)|^2 ds.$$

Hence the substitution corresponding to $x'(s) = \alpha(-s)x(s)$ is bounded, and $M_A \leq M$.

Suppose now that the Laurent substitution A has an inverse A^{-1} . Since the value of the Hermitian form (20) must then be at least $1/M_{A^{-1}}^2$ for every system (x_k) with $\sum_k |x_k|^2 = 1$, we may suppose

$$|\alpha(s)| \geq \frac{1}{M_{A^{-1}}}.$$

Thus $1/\alpha(s)$ is bounded and summable. Denote its coordinates by $\alpha_k^{(-1)}$. The matrices (α_{k-i}) and $(\alpha_{k-i}^{(-1)})$ plainly satisfy the general relations between the coefficients of inverse substitutions. Hence *the inverse A^{-1} is the Laurent substitution corresponding to the function $1/\alpha(s)$.*

More generally, *the inverse of $\lambda E - A$, when it exists, is given by the coordinates of the function $1/[\lambda - \alpha(s)]$; and, conversely, if this function is bounded, or can be made bounded after neglecting values of s forming a set of measure zero, the inverse $(\lambda E - A)^{-1}$ exists.*

In particular, if $\alpha(s)$ is continuous, the set of values λ for which the inverse of $\lambda E - A$ does not exist coincides with the set of values taken by $\alpha(s)$. If the doubly infinite series $\sum_k \alpha_k z^k$ converges in a circular annulus containing $z = 1$, the singular values of λ are the values taken by the series on $|z| = 1$; this set is therefore an analytic curve.⁹

115. Suppose now that $\alpha(s)$ is real, which is plainly equivalent to $\alpha_{-k} = \overline{\alpha_k}$ for every k . Consider the Hermitian form

$$A(x, x) = \sum_{i,k=-\infty}^{+\infty} \alpha_{k-i} x_i \overline{x_k} = \int_{-1/2}^{1/2} \alpha(s) |x(s)|^2 ds. \quad (21)$$

Let M be the upper bound of $\alpha(s)$ in Lebesgue's sense; that is, let M be the least number for which the set of s satisfying $\alpha(s) > M$ has measure zero. Define the lower bound m analogously. When the Hermitian form (21) is varied subject to

$$E(x, x) = \sum_{k=-\infty}^{+\infty} |x_k|^2 = \int_{-1/2}^{1/2} |x(s)|^2 ds = 1, \quad (22)$$

its values plainly remain between m and M . Conversely, let $\varepsilon > 0$ be arbitrarily small. The set on which $\alpha(s) > M - \varepsilon$ has a nonzero measure μ ; put $x(s) = 1/\sqrt{\mu}$ on this set and zero elsewhere. The coordinates of this function satisfy (22), and (21) gives

$$A(x, x) \geq M - \varepsilon.$$

An analogous argument applies to the lower bound m . Hence *the upper and lower bounds of $\alpha(s)$, in Lebesgue's sense, are also the exact bounds of the Hermitian form $A(x, x)$.*

In particular, a necessary and sufficient condition that $\alpha(s)$ be nonnegative, or can be made nonnegative after neglecting a set of measure zero, is that the Hermitian form $A(x, x)$ be nonnegative.

116. The preceding results apply immediately to the problem of determining the two bounds of a real function $\alpha(2\pi s)$ given by its Fourier expansion

$$\frac{1}{2}a_0 + \sum_{k=1}^{\infty} (a_k \cos 2\pi ks + b_k \sin 2\pi ks), \quad (23)$$

⁹Toeplitz gave a detailed and very interesting study of the special matrices corresponding to actual Laurent series in the last of the works cited above.

whose coefficients are given by the familiar formulas^y

$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \alpha(t) \cos kt \, dt, \quad b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \alpha(t) \sin kt \, dt.$$

Without concerning ourselves with whether the Fourier series converges, we agree to regard it as a symbol for the function which gives rise to it. The coefficients a_k, b_k play the role of coordinates. The coordinates relative to $[\varphi_k(s)]$ are obtained by putting

$$\alpha_0 = \frac{1}{2}a_0, \quad \alpha_k = \frac{1}{2}(a_k - ib_k), \quad \alpha_{-k} = \overline{\alpha_k} = \frac{1}{2}(a_k + ib_k).$$

To determine the bounds of $\alpha(2\pi s)$, we therefore consider the Hermitian form (21) formed with these quantities α_k .

Let m_n and M_n denote the bounds of the section

$$[A(x, x)]_n = \sum_{i,k=0}^n \alpha_{k-i} x_i \overline{x_k}, \quad (24)$$

where the x_k vary subject to

$$\sum_{k=0}^n |x_k|^2 = 1.$$

More generally, consider the sections

$$[A(x, x)]_{l,n} = \sum_{i,k=l}^n \alpha_{k-i} x_i \overline{x_k}, \quad l < n.$$

Since the coefficient matrix depends only on $n - l$, their bounds are m_{n-l} and M_{n-l} . Plainly,

$$m_n \geq m, \quad m_n \geq m_{n+1}, \quad M_n \leq M, \quad M_n \leq M_{n+1}.$$

Suppose that for some system (x_k) , the Hermitian form (21) comes within ε of its upper bound M , and put

$$x_k^{(n)} = \frac{x_k}{\left(\sum_{i=-n}^n |x_i|^2\right)^{1/2}} \quad (k = -n, -n+1, \dots, n),$$

^yTranslator's note: In the printed display, the sine term in (23) has b instead of b_k , and the coefficient formulas use $\alpha(2\pi s)$ while integrating from $-\pi$ to π . The evident typographical errors have been corrected by writing b_k and using the dummy variable t in the standard coefficient formulas. The printed identifications of α_k and α_{-k} also reverse the signs of ib_k ; since $\varphi_k(s) = e^{2\pi iks}$, those signs, and the corresponding signs in the determinant below, are corrected here.

with $x_k^{(n)} = 0$ for all other indices. The relation ^z

$$\lim_{n \rightarrow \infty} [A(x^{(n)}, x^{(n)})]_{-n, n} = A(x, x)$$

shows that, for sufficiently large n , $[A(x^{(n)}, x^{(n)})]_{-n, n} > M - 2\varepsilon$. Hence $M_{2n} > M - 2\varepsilon$; since M_n is nondecreasing and never exceeds M , it follows that $M_n \rightarrow M$. The analogous argument gives $m_n \rightarrow m$, or equivalently

$$m_n \longrightarrow m, \quad M_n \longrightarrow M.$$

By a familiar theorem, the bounds m_n and M_n of the Hermitian form (24) are respectively the smallest and largest roots ^{aa} of the determinantal equation

$$\det \begin{pmatrix} \alpha_0 - x & \alpha_1 & \alpha_2 & \cdots & \alpha_n \\ \alpha_{-1} & \alpha_0 - x & \alpha_1 & \cdots & \alpha_{n-1} \\ \vdots & \vdots & \vdots & & \vdots \\ \alpha_{-n} & \alpha_{-n+1} & \alpha_{-n+2} & \cdots & \alpha_0 - x \end{pmatrix} = 0.$$

In summary, the upper and lower bounds, in Lebesgue's sense, of the function $\alpha(2\pi s)$ having expansion (23) are, as $n \rightarrow \infty$, the limits of the largest and smallest roots of

$$\det \begin{pmatrix} a_0 - 2x & a_1 - ib_1 & \cdots & a_n - ib_n \\ a_1 + ib_1 & a_0 - 2x & \cdots & a_{n-1} - ib_{n-1} \\ \vdots & \vdots & & \vdots \\ a_n + ib_n & a_{n-1} + ib_{n-1} & \cdots & a_0 - 2x \end{pmatrix} = 0.$$

117. Let us finally observe that these beautiful results of Toeplitz form part of a group of theorems, due to several authors, more or less closely connected with Laurent matrices and all belonging to the line of thought of the important and well-known work of Landau and Carathéodory on Picard's celebrated theorem.¹⁰

^zTranslator's note: The French original uses the subscript n here and in the next inequality, although $x^{(n)}$ is supported on the indices $-n, \dots, n$. The section is therefore $[A]_{-n, n}$, whose upper bound is M_{2n} .

^{aa}Translator's note: The printed French reverses "largest" and "smallest" at this point; the order has been corrected to agree with the definitions of m_n and M_n .

¹⁰Cf. the communications of Toeplitz, Carathéodory, Fejér, and Fischer, *Rendiconti del Circolo Matematico di Palermo*, vol. XXXII (1911), pp. 191–256; G. Herglotz, *Berichte der Königlich Sächsischen Gesellschaft der Wissenschaften zu Leipzig*, vol. LXIII (1911), pp. 501–511; and I. Schur and G. Frobenius, *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften* (1912), pp. 4–31.

We shall indicate the principal facts briefly. By Picard's theorem, a nonconstant entire function takes every prescribed finite value, with at most one exceptional value. This theorem, discovered in 1879, was deepened in an unexpected way by Landau in 1904. Landau proved that, to determine a circle $|z| < R$ in which a convergent power series

$$a_0 + a_1 z + \cdots, \quad a_1 \neq 0,$$

takes at least once one of the values 0 or 1, it is enough to know only the first two coefficients a_0, a_1 . In the following year, Carathéodory gave the exact value of R as a function of a_0, a_1 . He was led to it by connecting this problem and a large class of analogous problems with the following one. The first $n + 1$ terms of the power series

$$\frac{1}{2} + c_1 z + c_2 z^2 + \cdots + c_n z^n + \cdots \quad (25)$$

are given; can the remaining terms be chosen so that the series converges throughout the disk $|z| < 1$ and the real part of the function it represents is everywhere positive?

Carathéodory's answer is the following. *The series (25) can be completed in the required manner if and only if the point*

$$y'_1 = c'_1, \quad y''_1 = -c''_1, \quad \dots, \quad y'_n = c'_n, \quad y''_n = -c''_n, \quad (c_k = c'_k + ic''_k),$$

of real $2n$ -dimensional space belongs to the smallest convex domain containing the closed curve defined parametrically by

$$y'_1 = \cos \theta, \quad y''_1 = \sin \theta, \quad \dots, \quad y'_n = \cos n\theta, \quad y''_n = \sin n\theta.$$

More recently, the investigations of Toeplitz just discussed supplied a purely algebraic answer to Carathéodory's question. Put $c_0 = 1$, $c_{-k} = \overline{c_k}$. Then *the series (25) can be continued in the required manner if and only if the Hermitian form*

$$\sum_{i,k=0}^n c_{k-i} x_i \overline{x_k} \quad (26)$$

is nonnegative.

The equivalence of the two conditions was also established by Carathéodory, E. Fischer, I. Schur, and Frobenius in the works cited above.

Suppose now that all coefficients of (25) are given. One may then ask whether the given series represents in $|z| < 1$ a function whose real part remains positive

there. This question was posed and solved independently by Carathéodory and by the author.¹¹ The answer is as follows: *the series (25) converges in $|z| < 1$, and the real part of the function it represents is everywhere positive, if and only if either of the two equivalent conditions just stated is satisfied for every integer n .*

Indeed, put $z = re^{2\pi is}$. The real part of (25) becomes

$$\frac{1}{2} + \sum_{k=1}^{\infty} (c'_k r^k \cos 2k\pi s - c''_k r^k \sin 2k\pi s), \quad (27)$$

and we require that, for $r < 1$, this series converge and represent a positive function. By no. 115, this requires the Hermitian form

$$\sum_{i,k=-\infty}^{+\infty} c_{k-i} r^{|k-i|} x_i \overline{x_k}$$

to exist and be nonnegative for every $r < 1$. In particular, its sections must be nonnegative for $r < 1$; on passing to the limit $r = 1$, the Hermitian forms (26) must therefore be nonnegative.

Conversely, suppose that (26) is nonnegative for every integer n . Put $x_0 = 1$, $x_1 = \dots = x_{n-1} = 0$, and $x_n = -c_n$.^{ab} Then (26) becomes $1 - |c_n|^2$; hence $|c_n| \leq 1$ for every n . It follows that (25), (27), and the series

$$\sum_{k=-\infty}^{+\infty} |c_k r^{|k|}|^2 \leq \sum_{k=-\infty}^{+\infty} r^{2|k|} = \frac{1+r^2}{1-r^2} \quad (28)$$

converge for every $r < 1$. Since (28) converges, the results of no. 115 apply; the harmonic function defined by (27) is therefore nonnegative for every $r < 1$. Finally, a harmonic function cannot attain its minimum in the interior of a domain in which it exists; hence the function (27) is positive for every $r < 1$.

Many other questions of this kind are treated in the works cited at the beginning of this paragraph, especially in the memoir of Carathéodory and Fejér.
